Sewage applied, 350 gallons, 6 times a week, until July 10; 450 gallons, 6 times a week, July 11 to December 21; 250 gallons, 6 times a week, December 22 to 31. Experiments interrupted by high water May 5 to 8 and May 18 to 20. Surface raked about 1 inch deep each week. September 25, about 2 inches of dirty sand scraped off and replaced by new material. December 2, surface spaded 6 inches deep. Canvas cover put on December 4. Snow removed during the winter months 17 times (63 inches total depth); ice removed 10 times (14.5 inches total depth).

**FILTER NO. 7.***Sub-surface Application of Sewage.*

This filter contains 44 inches of mixed coarse and fine sand like that in No. 6, above which are 10 inches of loam and 6 inches of soil. The sewage is applied in a circular pipe 6 inches in diameter and 18 inches below the surface, with open joints every 2 feet. At the beginning of the year the inlet to this pipe was trapped. After cleaning and relaying this pipe in October, 1892, the sewage was applied without difficulty during the winter months at the rate of 40,000 gallons per acre daily for six days in a week. The nitrification was very incomplete and the effluent contained very high free ammonia. It was thought that the ventilation was interfered with by the rain and melted snow which accumulated upon and at times froze to the surface. On March 15 the quantity of sewage was reduced to 20,000 gallons, but nitrification disappeared entirely

and a reducing action set in, showing that the filter was overdosed. The application of sewage was stopped on April 17 and the sub-surface pipe dug up April 26. In places the accumulated sludge more than half filled the pipe. Analyses showed that this sludge was equivalent to 75 per cent. of the insoluble albuminoid ammonia applied since the pipe was last cleaned. The pipe was relaid without the trap on July 8 and sewage applied at the rate of 40,000 gallons per acre daily for six days in a week. The pipe gradually clogged and the full dose could not be applied after December 1. The nitrification was very high in July, indicating a removal of stored organic matter, but became incomplete in August. Ventilation was increased by aspiration after September 1 and the quality of the effluent improved and remained very satisfactory throughout the year.

For a summary of the information obtained from the experiments upon the sub-surface application of sewage see page 425.

Sewage applied, 200 gallons, 6 times a week till March 10; 100 gallons, 6 times a week, March 11 to April 15. None applied April 17 to July 8; 300 gallons, 6 times a week, July 10 to Nov. 20, after which the quantity which could be applied decreased to less than 200 gallons a week. April 26, drain pipe removed and cleaned, replaced without trap at inlet, July 8. Air drawn through filter twelve hours each day, September 1 to October 20. Air drawn constantly through the filter from October 28 to November 17, and from December 2 to December 23.

## FILTER No. 9 A.

This filter was protected from the weather by a canvas cover and took sewage without difficulty at the rate of 120,000 gallons per acre daily for six days in a week. The surface was not raked, but scraped when necessary, to relieve clogging. The quality of the effluent deteriorated during January, but began to steadily improve in the latter part of February. On March 6 the canvas was removed and the surface scraped. During April, May and June the effluent was very well purified and there was a removal of organic matter stored in the sand. The purification remained satisfactory until November, when sub-surface clogging appeared. The results obtained upon this filter which are presented below are discussed on page 414.

Sewage applied, 600 gallons, 6 times a week until December 22, when 300 gallons began to be applied 6 times a week. Surface protected by canvas cover till March 7. Dirty sand scraped from surface March 7, March 14, April 24, July 31, September 1, September 23, October 21, November 6, 16, 18, 20, 21, 22. Filter restored to original depth with clean sand March 14, September 25. The sand removed November 16 to 22 with ½ inch of new sand replaced December 2. Experiments interrupted by high water May 18 to 20. Weeds cut July 13, and pulled up July 31.

## FILTER NO. 11 A.

This filter contains 5 feet of mixed coarse and fine sand which had become clogged and had been removed from the surface of Filter No. 6. Sewage was applied at the rate of 60,000 gallons per acre daily for six days in a week. The effluent was well purified during the winter but began to deteriorate the later part of March, and nitrification decreased steadily. This was caused by incomplete ventilation as the scum at the surface was too thick to dry and crack between doses. Aspiration was tried in July and gave some relief, but to insure permanent improvement the upper 3 inches were removed on August 16, and aspiration tried until September 22. The effluent was very well purified in September and showed a removal of organic matter stored in the sand. The quality of the effluent remained satisfactory through the rest of the year in the absence of aspiration.

For a discussion of this experiment see page 426.

Sewage applied, 3 gallons, 6 times a week. Surface raked 3 inches deep each week. Air drawn through sand from July 10 to 20; eighteen hours a day July 31 to August 31, and continuously September 1 to 22. Experiments interrupted by high water March 16, May 5 to 8 and 18 to 20. August 14, 3 inches removed from surface.

## FILTERS NOS. 12 A, 15 B AND 16 B.

Filter No. 12 A contains 60 inches in depth of fine sand, and has received the effluents of Filters No. 15 B and 16 B which are filled with coarse gravel. An aspirator was attached to No. 15 B on March 18, and to No. 16 B on January 16. The rate of filtration has been very high for each of these filters—equivalent to 480,000 gallons per acre daily for six days in a week, for the last seven months. The surfaces of these gravel filters were not disturbed until July, 1893, about a year after they were first put in operation. They were raked 3 inches deep once a week after September 1, and daily after October 26. The quality of the effluent was found by series of analyses to be closely dependent upon the current of air drawn through the gravel. Toward the end of the year it was found that the ventilation was less complete than usual, owing to a leak around the outlet pipe. This doubtless explains, to a great extent, the deterioration in the quality of the effluent and also the clogging of the gravel, which necessitated raking on several occasions to a depth of 6 inches.

The effluents of these gravel filters were uniformly well purified by No. 12 A, when operated at a rate of 960,000 gallons per acre daily for six days in a week. Since March 24 the surface has been scraped when necessary to relieve clogging, and has not been raked. It was scraped on an average once in five days, and the average depth removed was 0.24 inch. The removed sand was washed and replaced. To do away with sub-surface clogging the filter was raked to a depth of 6 inches on September 27, December 12 and 27. The deterioration in the quality of the effluents of Filters No. 15 B and 16 B in December, began to make itself apparent toward the end of the year, in the operation of this filter.

These results are discussed on page 422.

*Effluent from Filter No. 12 A.*

Sewage applied, 3 gallons 24 times a week, till February 12; 3 gallons 36 times a week, February 13 to May 14; 4 gallons 36 times a week from May 15 to June 11; 5 gallons 36 times a week, June 12 to 25; 4 gallons 36 times a week, June 26 to October 22; 2 gallons 72 times a week from October 23 to December 31. Experiments interrupted by high water March 15 to 17; May 4 to 9; May 18 to 21; Air drawn through gravel January 16 to December 31. Surface raked 3 inches deep 4 times from July 18 to September 1 and each week from September 1 to October 26; 3 inches deep daily, October 26 to December 31, with the following exceptions: 8 inches deep, December 12, and 6 inches deep, December 30.

## FILTER No. 13.

This filter was used during the winter months for confirmation of experiments to determine the effect of nitrification upon the removal of bacteria by filtration. Beginning March 22 sewage was applied at the rate of 160,000 gallons per acre daily for six days in a week. This was done with a view to obtaining, in conjunction with Filter No. 14, some comparable results upon the removal of dyestuffs from sewage by filters of coarse sand with and without the presence of polarite. These results are summarized on page 427.

Three gallons effluent from Filter No. 18 A applied, 6 times a week, till March 21. Eight gallons sewage applied, 6 times a week, March 22 to September 27. Forty-four hundredths parts per 100,000 of Scarlet 2R applied in sewage, August 26 to September 7. Sand washed September 9, by applying city water, to remove traces of Scarlet 2R, and 0.33 parts per 100,000 of Patent Blue applied in sewage, September 23-27. Experiment discontinued September 27.

## FILTER No. 13 A.

This filter contains 60 inches in depth of sand of an effective size of 0.19 millimeter, and was constructed on September 27, 1893. It has received the supernatant liquid from sewage which had been allowed to settle four hours. The surface, which has been scraped when necessary to relieve clogging and not raked, was scraped on an average once in six days, and the average depth removed was 0.37 inch. Owing to sub-surface clogging it was necessary to spade over the surface 6 inches deep three times in December. It appeared that the rate of filtration, 480,000 gallons per acre daily for six days in a week, overtaxed the capacity of the filter, which was allowed to rest for two weeks beginning December 23. The results are discussed on page 423.

Sewage (settled 4 hours) applied, 6 gallons 18 times a week, September 27 to October 22; 3 gallons 48 times a week, October 23 to December 23, after which none was applied. Surface scraped and sand of previous scraping (after washing) replaced on following dates: October 9, 21, 27, November 1, 7, 13, 17, 24, 28, 30, December 5, 7, 18. Spaded over 6 to 7 inches deep, December 2, 12, 19.

## FILTER No. 14.

This filter is 63 inches deep and contains sand of an effective size of 0.48 millimeter. On January 21, 1893, the upper 6 inches of partially clogged and discolored sand were removed; the next 7 inches were taken out and, after putting in 7 inches in depth of polarite, were used to fill the filter to its original depth. The chief experiment was upon the removal of color from sewage containing dye-stuffs, which is summarized on page 427.

The rate of filtration was 160,000 gallons per acre daily for six days in a week until October 23 when the rate was doubled. The quality of the effluent was uniformly good until the middle of November, when clogging occurred at the surface of the polarite. The filter was allowed to rest from November 16 to December 4, when sewage was again applied at the rate of 160,000 gallons. The effluent was well purified, but clogging began to gradually reappear.

Sewage applied, 8 gallons 6 times a week, till October 22; 8 gallons 12 times a week, October 23 to November 16; 8 gallons 6 times a week, December 4 to December 31. Color applied in sewage February 13 to March 22 and August 26 to September 28. Experiments interrupted by high water March 15 to 17; May 4 to 9; May 18 to 21. Surface raked 3 inches deep each week.

## FILTER No. 17 A.

This filter of medium fine sand, with four layers of marble dust, received during the entire year sewage to which sulphuric acid equal to 49 parts in 100,000 of actual  $H_2SO_4$  was added. The rate of filtration was 60,000 gallons per acre daily for six days in a week. The free ammonia in the effluent began to increase in November, 1892, and was unusually high during the greater part of 1893. This increase, as well as that of the albuminoid ammonia, was owing to an interruption in ventilation caused by clogging. To remedy this the upper layer of marble dust, about 3 inches below the surface, in July, and later the sand above this layer, were replaced with new materials. It was found that the original layer of marble dust had occasionally been disturbed in the weekly raking and this treatment gave only temporary relief. Clogging again occurred in September, nitrification was very incomplete, and there was present a reducing action, as the sand down to the second layer of marble dust (12 inches) was very black with iron sulphide. A thin layer was scraped from the surface of the second portion of marble dust in October and the old sand replaced. The quality of the effluent steadily improved and in December was excellent.

Three gallons of sewage plus sulphuric acid equal to 49 parts per 100,000 applied 6 times a week. Surface raked 3 inches deep each week. Experiments interrupted by high water March 15 to 17, May 4 to 9, May 17 to 21. July 12, upper layer of marble dust replaced by a fresh layer. August 16, upper 3 inches of sand replaced by fresh sand. September 29, upper layer of marble dust disturbed. October 21, marble dust and upper 3 inches of sand removed. October 25, 9 inches of sand removed and second layer of marble dust scraped; sand replaced with 3 inches of clean material.

## FILTER No. 19.

This filter of medium fine sand has received since January 20, 1893, the supernatant liquid from sewage which was allowed to settle for four hours after treatment with alum at the rate of 1,000 pounds per million gallons. The rate of filtration was 120,000 gallons per acre daily for six days in a week up to June 12, after which the rate was increased from time to time until it became 640,000 gallons on and after October 23. From April to August, inclusive, the quality of the effluent was excellent, but the ammonias began to increase in September and continued to do so during the rest of the year. Since October 23 the surface has been scraped to relieve clogging. It has been scraped on an average once in ten days, and the average depth removed was 0.47 inch. On December 2 and 12 the surface was spaded over, 6 inches deep, to relieve clogging. This clogging and the deterioration in the quality of the effluent indicated that this high rate of filtration when long continued overtaxed the capacity of the filter which was allowed to rest for two weeks beginning December 23. See page 422 for a discussion of these results.

*Effluent from Filter No. 19.*

Six gallons of chemically clarified sewage applied 6 times a week, till June 11; 8 gallons 6 times a week, June 12 to July 30; 6 gallons 12 times a week, July 31 to August 31; 4 gallons 36 times a week, September 1 to October 22; 4 gallons 48 times a week, October 23 to December 23, after which none was applied. Experiments interrupted by high water March 15 to 17, May 4 to 9, May 18 to 21. Surface raked 3 inches deep each week until October 23, after which surface was scraped and sand of previous scraping (after washing) replaced on following dates: November 3, 13, 18, 22, 23. Spaded, 6 inches deep, December 2, 12. October 6, upper 4 inches removed and replaced with fresh sand.

## FILTER No. 25.

In this filter was buried on December 18, 1889, the carcass of a dog above 5 feet of sand and loam and beneath 6 feet of sand, loam and soil, as was described in the Special Report upon the Purification of Sewage and Water (page 689). Since May 9, 1892, city water has been applied at the rate of 60,000 gallons per acre daily for six days in a week. There was a marked improvement in the chemical quality of the effluent in 1892, but the numbers of bacteria increased. In 1893 there have been no marked changes in the chemical characteristics of the effluent, and while the numbers of bacteria have been quite variable, they have averaged considerably lower than during the latter part of the preceding year. The effluent has been uniformly discolored by iron. The odor and turbidity have been very much less marked than formerly, but are still perceptible.

*Effluent from Filter No. 25.*

Outlet pipe trapped. City water applied in 3 gallon doses once a week until May 9, 1892, and since that time 6 times a week. Experiment interrupted by high water March 15 to 17, May 4 to 9 and May 18 to 22, 1893. Surface scraped July 10, 1893. The applied water froze on the surface several times during the severest winter weather and was removed.

## FILTER No. 30.

This filter contains 30 inches in depth of coarse sand of an effective size of 0.48 millimeter. It has received sewage at a uniform rate of 55,800 gallons per acre daily for six days in a week with satisfactory results. No disturbance of the material, other than the weekly raking, has taken place since the filter was first put in operation, May 31, 1890.

Sewage applied, 2 gallons 6 times a week. Surface raked 3 inches deep each week. Experiments interrupted by high water May 4 to 8; May 18 to 20.

## FILTER No. 31.

This filter contains 30 inches in depth of medium fine sand of an effective size of 0.17 millimeter. It has received sewage at a uniform rate of 55,800 gallons per acre daily for six days in a week. The effluent has been uniformly well purified. No disturbance of the material, other than the weekly raking, has taken place since the filter was first put in operation May 31, 1890.

*Effluent from Filter No. 31.*

Sewage applied, 2 gallons 6 times a week. Surface raked 3 inches deep each week. Experiments interrupted by high water May 5 to 8; May 18 to 20.

## FILTER No. 32.

This filter contains 30 inches in depth of medium fine sand of an effective size of 0.17 millimeter. It received the supernatant liquid from sewage treated by chemical precipitation like that applied to No. 19 at the rate of 112,000 gallons per acre daily for six days in a week. This rate was doubled on June 12 and that rate doubled October 23 (446,000 gallons). The filter became clogged in spite of frequent raking and scraping; this, with the deterioration in the quality of the effluent, indicated that this rate of filtration overtaxed the capacity of the filter, which was allowed to rest for two weeks beginning December 23.

*Effluent from Filter No. 32.*

Surface raked 3 inches deep each week until October 21. Experiments interrupted by high water May 5 to 8; May 18 to 20. Four gallons chemically clarified sewage applied, 6 times a week, till June 11; 2 gallons 24 times a week, June 12 to October 22; 2 gallons 48 times a week, October 23 to December 23, after which none was applied. Surface spaded 6 inches deep, November 20, December 12 and December 21. Surface scraped, and sand of previous scraping replaced (after washing) on following dates: October 21, November 7, 17, 24, 29, December 2, 18 and 21.

## FILTRATION OF WATER.

---

One of the chief objects of water filtration, in most cases, is a removal of the disease-producing germs. The investigations by the Board in 1892 indicated that it is possible to construct filters which will yield 2,000,000 gallons of water per acre daily, and remove 99.5 per cent. of the bacteria in the applied water. The investigations were continued in 1893 with the view to learn the efficiency of the filters as they continued in service, and also to learn the bacterial efficiency of filters of coarser sands operated at higher rates of filtration.

The general plan of the experiments was the same as in 1892. Examination of the bacterial contents of the river water and of the effluent of each filter were made daily throughout the year. Owing to complications from freezing, which caused the formation of channels at the sides of the iron filter tanks during the winter months, and to the evolution of air by the saturated water within the filters, the results obtained from May to November, inclusive, alone will be discussed. Beginning May 12 *B. prodigiosus* was regularly applied to the filters ten hours daily and the effluent of each filter examined four or more times daily, at the time when the applied water containing this germ is passing through the outlet pipes. The reason that this germ was used is because it is easy to differentiate it from ordinary water bacteria and in its mode of life in the river water it appears to be very similar to the germ generally recognized as the cause of typhoid fever. In the table below is given a summary of the results obtained from the several filters. In the case of the older filters (Nos. 18 A to 42) the averages include all of the results; in the case of the remaining (new) filters the averages include all results after the second week of operation, when the efficiency in most cases became normal. The diameter of all of these filters is twenty inches and the area of filtering surface is equal to one twenty-thousandth of an acre. A detailed account of these results will be found beyond.

Summary of Bacterial Results obtained from the Several Water Filters, May 12 to Dec. 2, 1893.

The results show that —

1. The bacterial efficiency of the older filters, all things considered, was as satisfactory in 1893 as it was during the preceding year.

2. A high degree of bacterial efficiency was attained by the new filters of coarser sand and operated at higher rates of filtration.

This is brought out more clearly by the following table, in which are summarized the results obtained from the newer and coarser filters for the four weeks ending December 2. The bacterial averages include the results of all examinations in each case and represent at least four samples daily taken at widely different hours.

The rates of filtration enclosed within the brackets are for the time when water was actually applied; the other rates are averages for the whole time, including the periods of rest.

These figures show that very good results were obtained from the newer experimental filters which were operated at much higher rates of filtration than those studied in 1892. This is particularly the case with Filters Nos. 43 and 44, which during the latter part of November were operated at rates of more than 9,000,000 gallons per acre daily, with a removal of over 98 per cent. of the applied water bacteria and over 99.5 per cent. of the applied *B. prodigiosus*.

### THE EFFECT UPON BACTERIAL PURIFICATION OF RATE OF FILTRATION OF WATER.

There are two views to this problem, first, the effect of differences in rates of filtration where the rate is kept constant after the change has once been made; and, second, the effect of fluctuating rates.

It is thought that the effect of changes in rates, which are regularly maintained after the change is made, is best shown by taking the average monthly results. The rates of filtration of the several filters were very seldom changed more than once in a month; they were not changed at all in some instances and all changes were moderate ones. When we consider the large number of bacteria stored in the sand the small differences in the number of bacteria in the applied water exert usually but little influence upon the numbers in the effluent and the results are therefore expressed in numbers per cubic centimeter.

*Average Monthly Results, showing the Number of Bacteria per Cubic Centimeter in the Effluents of the several Water Filters.*  
 [Rates expressed in million gallons per acre daily.]

In the case of No. 18 A the number of bacteria in the effluent increased about the middle of July after removing the siphon which delivered the water in one-quart doses onto the sand about once in four minutes days, nights and Sundays. After this time the water was applied sixteen hours a day and the filter allowed to drain during the remaining hours. Some of the bacterial increases during the summer were due to growths or to conditions favoring longer continuance of life of the bacteria in the sand. This was more marked in continuous than in intermittent filters.

In some cases there were marked increases in the number of bacteria in the effluent, evidently not due to changes in rates of filtration, and which at present cannot be fully accounted for. In other instances, such as Nos. 43 and 44, an increase in the rate was followed at times by no increase whatever in the number of bacteria in the effluent; and, when studied by weeks, some of the results indicate a diminution. These results, taken all together, indicate that in the process of water filtration there exist conditions which exert more influence upon the bacterial contents of the effluent than do differences in rates of filtration within moderate limits. Some of the conditions appear to be normal to the operations of these experimental filters while others are not yet understood. Upon examination of the results obtained at the highest rates, however, it will be seen that the bacterial efficiency diminishes and the statement made in earlier reports that low rates are safer than high rates is undoubtedly true. Nevertheless, up to a certain limit the rate apparently exerts very little influence, and this limit is different for different filters and also varies with other conditions in the case of the same filter.

*The Immediate Effect upon Bacterial Purification of Increasing the Rate of Filtration.*

In the next table are given the results obtained from each filter with regard to this point. Fluctuations in the rate of filtration appear to be an important feature in the operation of some of the older filters in Europe and the following results have been obtained at the Experiment Station upon this subject. The number of bacteria per cubic centimeter for each of the three days before and the three days after increasing the rate of filtration are given in each case where there was no complication such as the effect of scraping. In most cases the rate was increased and practically no information has

been obtained as to the effect of decreasing the rate. As the changes were usually made on Monday there are very few results for the first day before increasing the rate.

These results show that in a majority of cases an increase in the number of bacteria in the effluent followed an increase, within these limits, in the rate of filtration. This is more noticeable in filters of coarse material than in those of fine, and shows an advantage of uniformity in the operation of water filters.

# THE EFFECT OF DEPTH OF MATERIAL UPON BACTERIAL PURIFICATION OF WATER.

The results upon this point are as follows : —

| NUMBER OF FILTER. | Depth.<br>Inches. | Effective<br>Size of<br>Grain.<br>—<br>Millimeter. | Period — 1893.     | Rate.<br>—<br>Million<br>Gallons<br>per Acre<br>Daily. | AVERAGE PER CENT. OF<br>NUMBER OF<br>APPLIED BACTERIA<br>WHICH APPEARED IN THE<br>EFFLUENTS. |                          |

The results obtained from Filters Nos. 44 and 46 show that the deeper filter is the more effective, although the filter one foot deep gave quite satisfactory results, especially at the lower rate of filtration. Upon consideration of the second series it is seen that No. 37, the deepest filter, was the most effective while the shallowest one, No. 39, was the least efficient in removing bacteria. No. 39 contained 5 inches of underdrain (stones, gravel and coarse sand) in addition to the inch of sand. Of the two filters, Nos. 38 and 42, 20 and 10 inches deep, respectively, the shallower was very slightly the more efficient. It is to be noted that when the filters were restored to their original depth, by the addition in some cases of a foot of sand, there was no apparent effect upon the bacterial contents of the effluents. We must conclude, however, all things considered, that while very satisfactory results may be obtained, under favorable conditions, from filters one to two feet deep, the deeper filters are safer than the shallower ones.

### THE EFFECT OF SIZE OF SAND GRAINS UPON BACTERIAL PURIFICATION.

In the following table is given a summary of the results obtained from the several filters during the month of November, this month affording the fairest comparison because the conditions were then most nearly alike.

#### *Continuous Filters.*

#### *Intermittent Filters.*

|                 |      |     |     |     |    |
|-----------------|------|-----|-----|-----|----|
| 41, . . . . .   | 0.14 | 16  | 1.6 | 10  | 1  |
| 45, . . . . .   | 0.23 | 42  | 3.6 | 120 | 12 |
| 47, . . . . .   | 0.29 | 67  | 3.6 | 213 | 25 |
| 48, . . . . .   | 0.38 | 116 | 2.9 | 123 | 23 |
| 18 A, . . . . . | 0.48 | 184 | 1.8 | 167 | 11 |

These results indicate that, within the limits in sizes of sand grains which would be ordinarily employed in filtration, the finer sands are slightly more efficient in removing bacteria than the coarser ones. It appears, however, that there are conditions sometimes attending the process of filtration which disguise and at times completely offset the slight advantages which arise from fineness of material.

### THE EFFECT OF SCRAPING FILTERS UPON BACTERIAL PURIFICATION OF WATER.

It was shown in the Annual Report for 1892 that there was a slight increase in the number of bacteria in the effluent after a filter had been scraped. The method of scraping the continuous filters followed

in 1892 was practised in 1893 until November 1, as follows: the water above the sand was siphoned off and the filter allowed to drain until the water stood about an inch below the surface of the sand. The outlet was then closed, the surface scraped and water applied slowly from the top. The intermittent filters were scraped after draining. In the table below is given a summary, up to November, of the number of bacteria in the effluent during each of the three days before and three days after scraping, and also of the remaining days of each period between scrapings. In some instances the filters were scraped about once a week and nearly all of the results are contained under the headings, three days before and three days after scraping; under these circumstances a representative result for the time midway between scrapings is given under the column, remaining days.

*Summary of the Average Results of the Number of Bacteria per Cubic Centimeter in the Effluent of each Filter during Different Portions of each Period between Scrapings.*

The average results from all of the filters indicate that there was a very slight decrease in bacterial efficiency, after scraping, by the method of operation practised. Taking the results individually it was found that out of 113 scrapings an increase in the number of bacteria in the effluents just after scraping, above that accounted for by the ordinary bacterial fluctuations, occurred in the case of the water bacteria 46 times and in the case of *B. prodigiosus* 55 times. Almost without exception the increase in number of bacteria was very slight, as will be seen in the table below, which contains the results obtained from each filter when the effect of scraping was most marked. In the second table beyond are given the results when the effect of scraping was the least marked in the case of each filter. During the period in which the results given in these tables were obtained the water bacteria in the applied water averaged 10,500 and the *B. prodigiosus* 7,000 per cubic centimeter.

*Table showing the Number of Bacteria per Cubic Centimeter in the Effluent of Each Filter during Different Portions of the Period between Scrapings when the Effect of Scraping was Most Marked.*

#### THE EFFECT UPON BACTERIAL PURIFICATION OF DISTURBING THE UPPER TWELVE INCHES OF FILTERS OF FINE MATERIAL.

Filters No. 33 A (continuous) and 41 (intermittent), containing 48 inches in depth of sand of an effective size of 0.14 millimeter, were scraped on July 17, after draining. This sand is so fine that the lower portion of the filter remains saturated after draining. The upper 12 inches of material were taken out and replaced. Water was applied at the top of the continuous filter, with the outlet closed, and after the surface was covered the faucet below was opened to give the usual rate of two million gallons per acre daily. The faucet of the intermittent filter was kept wide open and the rate of filtration regulated at the top.

In the following table are given the bacterial results from these filters for the week preceding and the week following this treatment. No *B. prodigiosus* was applied on July 17; the results on that day represent drainings. On all other days the results are averages of four examinations.

*Bacteria per Cubic Centimeter.*

THE EFFECT UPON BACTERIAL PURIFICATION OF REMOVING AN INCH LAYER OF LOAM TWO INCHES BELOW THE SURFACE OF AN INTERMITTENT FILTER OF MEDIUM FINE SAND.

Filter No. 35 A contained 48 inches in depth of sand of an effective size of 0.20 millimeter. After draining, on July 17 the surface was scraped, the loam layer 2 inches below the surface taken out and the sand replaced. The faucet below was kept wide open and the rate of the applied water regulated at the top. The bacterial results before and after this treatment were as follows:—

*Bacteria per Cubic Centimeter.*

The results presented in the last two tables indicate that a slight decrease in bacterial efficiency follows a mechanical disturbance of the upper portion of fine filters and the removal of a layer of fine loam. From our general knowledge of the efficiency of coarser

filters it is probable that in such cases the diminution would be more marked. The effect of mechanical disturbance is brought out most clearly by the results obtained from Filters Nos. 3 B and 8 A.

These filters are one two-hundredth of an acre in area and contain five feet in depth of sand of an effective size of 0.23 millimeter. Filter No. 3 B has been operated intermittently at an average rate of two million gallons per acre daily since September 23, as follows: at 5 A.M. the gate on the outlet pipe is closed and the water turned on at the top near the edge. When the filter is covered (about 7.30 A.M.) the gate on the outlet pipe is opened to give the prescribed rate of filtration, and the surface is kept covered until 9 P.M. when the water is shut off and the filter allowed to drain during the night. No. 8 A has been operated continuously since September 26 at a constant rate of two million gallons per acre daily. While the passage of water through No. 8 A is uniform and causes no disturbance of the sand, the peculiar method of daily filling in No. 3 B drives out a large part of the air contained in the sand and causes more or less disturbance of the sand at the surface. That this disturbance of the surface is due to the escape of air from the sand can be readily seen from inspection, and is further indicated by the fact that up to January 1, No. 8 A was scraped three times to relieve clogging, while No. 3 B was not scraped at all during this period, although it yielded as much water. In the table below are given the average results of daily bacterial examinations of samples taken at different hours during the day from the effluent of each filter, from October 30 to December 8. The number of bacteria per cubic centimeter in the applied water averaged 8,800 during this period.

| Per cent. of number of applied bacteria which appeared in effluents, | 3.63                                          | 3.25    | 2.10   | 1.59   | 1.18                                        | 1.35    | 1.48   | 1.17   |

The diminished efficiency of No. 3 B in the forenoon appears to be due to the mechanical disturbance of the main body of the sand by the escaping air.

### THE EFFECT UPON BACTERIAL PURIFICATION OF FREEZING THE SURFACE LAYERS OF A FILTER.

The freezing of the upper layers of a filter which has been drained also appears to aid in causing the passage of more bacteria through the filter. The weather during the second and third week in December was very cold and the surface of No. 3 B froze during the night after draining. The last week in the month was much warmer. Upon comparison of the results below with those presented above it will be seen that No. 3 B was less efficient than usual during the severe weather, but the results became normal again when warmer weather appeared.

### EFFECT UPON BACTERIAL PURIFICATION OF RAPIDLY FILLING FILTERS FROM BELOW AFTER DRAINING.

During November several of the small filters, when their pores contained more or less air, were filled from below with filtered water. It is not known definitely how fast the water flowed into the filters, but in a majority of cases the rate was high, — probably equivalent to 5,000,000 gallons per acre daily or more.

More information is needed upon this point, but from the results given below it is clear that by rapidly filling a filter from below it is possible to disturb the sand so that the bacterial efficiency will be much diminished upon resuming filtration.

In the case of the several filters in question the numbers of bacteria in the effluents during the three days before and three days after filling from below are as follows: —

*Average Daily Numbers of Bacteria per Cubic Centimeter.*

| 49, . . . . .     | 26              | -           | 46         | 176            | 69          | 91         | 5.0                   | -           | 13.0       | 69.0           | 16.0        | 25.0       |

In some instances only a very small portion of water, applied after the filter was put in operation after filling from below, appeared during that day as effluent. Under such circumstances the bacteria were lower than on the following day.

Some experiments have been made upon Filter No. 8 A, in which the filter, after scraping, was filled from below with city (filtered) water at a rate not exceeding 1,500,000 gallons per acre daily. The results thus far obtained indicate that no diminution in the bacterial efficiency follows this operation.

## CONCLUSIONS.

From the evidence at hand it appears fair to conclude that—

1. No appreciable diminution in the bacterial efficiency of the experimental filters followed scraping, provided there was no mechanical disturbance of the main body of the sand.

2. Filters may be scraped without interfering with their bacterial efficiency by draining the water slightly below the surface of the sand and, after scraping, slowly filling from the top.

3. Filters may be drained and slowly filled from below, after scraping, without diminishing their bacterial efficiency.

4. When filters are drained and filled quickly from below, after scraping, there is an increase in the number of bacteria in the effluent.

5. When filters are drained and filled rapidly from the top a disturbance of the sand follows in the case of some of the experimental filters, which causes a diminution in the bacterial efficiency.

# THE EFFECT UPON BACTERIAL PURIFICATION OF THE AMOUNT OF LOSS OF HEAD.

In some places abroad it is believed that the bacterial efficiency of a filter decreases as the loss of head increases beyond a certain limit. For this and other reasons several of the most recently constructed water filters in Germany are so arranged that the available head is very much less than the total depth of water and sand; in fact, in some instances the available head is less than 2.5 feet. The Lawrence results obtained in 1892 have been arranged to throw light upon this subject and are presented in the table below. In all cases these filters were scraped when the loss of head equalled the total depth of sand and water; and it was just before scraping, of course, that the loss of head approximated the maximum. The next table shows the average number of bacteria per cubic centimeter in the effluent during the three days before and the three days after scraping each filter, as well as the numbers during the intermediate days, that is, the remaining days of each period between scrapings. Owing to the growth of bacteria in some of the filters during mid-summer (see Annual Report for 1892, page 530) the results are divided into three periods, viz.: spring, summer and fall. It may also be stated that the numbers of bacteria in the effluents during each of the three days before scraping were substantially the same with the exception of a few instances in mid-summer when the bacterial growths occurred.

*Summary of Results showing Uniformity of Bacterial Purification by Water Filters during Periods between Scrapings—1892.*

These results show that during the spring and fall there was no diminution in the bacterial efficiency of these experimental filters as the loss of head approached and reached the maximum (total depth of water and sand); neither was there any apparent difference in this regard between those filters which had a maximum loss of head of 70 inches and those in which the maximum loss was less than half of this amount. It will be seen that during midsummer the highest number of bacteria in the effluent in some cases did appear when the loss of head was greatest. This was undoubtedly due to the conditions existing in the filter which favored the continuance of life and growth of certain species of bacteria, and the high numbers occurred just before scraping and when the loss of head was greatest, because the accumulation of organic matter (food) was largest at that time.

The average results obtained from all of the small water filters in 1893 with regard to this point are presented in the table on page 463. These averages contain all results, including those of midsummer, when the abnormal growth of bacteria occurred within the filters. This growth, however, was much less marked than in 1892. The final averages for 1893 confirm the results obtained during the preceding year and show clearly that with these experimental filters, under the existing methods of operation, there is ordinarily no appreciable diminution in the bacterial efficiency caused by increases in loss of head up to 70 inches.

In the case of the continuous Filter No. 8 A (one two-hundredth of an acre in area) there were several occasions, notably December 1 and 29 (see beyond), when the number of bacteria increased in the effluent, just before scraping, and the loss of head reached the total depth of the filter. There was no trap on the outlet pipe of this filter, and the bacteria in the effluent did not increase until the loss of head had practically reached the maximum and when there was not enough pressure on the open gate to cause the prescribed quantity of effluent to pass. Under these circumstances air entered the filter through the outlet pipe, and the water probably filtered through the sand in certain places of least resistance at a relatively high rate. It is believed that these results are very exceptional and caused by the entrance of air from below through the untrapped outlet. It is of importance to note that the bacterial results were normal so long as there was any pressure upon the outlet gate in excess of that necessary for the passage of the prescribed quantity

of water. Furthermore, the outlet was kept trapped at later dates and no increase in the numbers of bacteria in the effluent was found just before scraping, although the scraping was deferred until the filter ran nearly dry.

It is also to be noted that in the case of the Lawrence city filter during January and February (see tables beyond) the number of bacteria in the effluent remained reasonably constant up to February 19, the date when scraping in sections began, although the loss of head increased from 3 to 7.6 feet.

#### THE EFFECT UPON THE BACTERIAL PURIFICATION OF THE METHOD OF APPLICATION OF WATER.

In comparing the efficiency of the intermittent with that of the continuous filters it is to be kept in mind that several different ways have been employed for allowing the entrance of air into the pores of the intermittent water filters. In most cases, up to October 1, 1893, the outlets of the intermittent filters have been untrapped and kept wide open, while the rate of filtration of water has been regulated at the inlet on the surface; these filters have been worked sixteen hours a day on six days in a week and allowed to drain the remainder of the time. Other filters, such as the older ones, No. 18 A and 20 A, also had the outlet untrapped and wide open, but received the contents of a small reservoir which was automatically discharged upon the surface at frequent and regular intervals, days, nights and Sundays. Beginning October 1, 1893, all of the intermittent filters have been operated as follows: at 5 A.M., after draining, the untrapped outlet has been closed and the water turned on at the top, which forces out the air at the surface. When the surface is covered and the air driven out of the pores of the sand (about 7.30 A.M.) the gate on the outlet pipe is opened to give the prescribed rate and the surface kept covered with water. At 9 P.M. the water is shut off at the top and the filter allowed to drain over night. In this method of operation there are two features which are not necessarily a part of intermittent filtration.

I. The actual rate of filtration during the hours the filter was operated was 50 per cent. higher than the average rate for twenty-four hours in order that the yield of effluent in sixteen hours should equal that of the continuous mate in twenty-four hours.

II. The exclusion of air from the pores of the sand by the manner of filling the filters and the resulting disturbance of the surface by the escaping air.

In studying the results obtained from the several pairs of intermittent and continuous filters, which are presented below, the different methods of operation of the intermittent filters are not to be forgotten, and are as follows: up to October 1 and from November 21 to 30 the intermittent filters, Nos. 41, 45, 47 and 48, were operated sixteen hours a day on six days in a week, with the outlet untrapped and wide open and the rate of filtration regulated at the inlet at the surface. During the rest of the period covered by these results the untrapped outlet was closed after draining and water applied at the top; when the surface was covered the outlet was opened to give the prescribed rate.

*Table showing a Comparison of the Number of Bacteria, per Cubic Centimeter, arranged as Weekly Averages, in the Effluents of each Pair of Continuous and Intermittent Filters.*

The results obtained from Filters Nos. 3 B and 8 A are instructive in this connection; the summarized and detailed results are given in tables which may be found beyond.

The results at hand, obtained from the several pairs of continuous and intermittent filters, show —

1. That in the case of the filters of very fine sand (in which there is a saturated layer of considerable depth) the bacterial efficiency was substantially the same by each method employed in the application of water during the greater part of the period, but during mid-summer (July 24 to September 2) the continuous filter allowed a few more of the hardy water bacteria, but not of *B. prodigiosus*, to pass through.

2. That with filters of coarser sands, operated at comparatively high rates, the continuous filters were ordinarily more efficient in removing bacteria than the intermittent filters under the existing methods of operation. The reason of this is that the actual rate of flow was lower and more uniform and there was no mechanical disturbance of the sand as was the case during the greater part of the period with the intermittent filters, owing to the manner of filling and driving out the air at the surface.

#### CHEMICAL PURIFICATION OF WATER BY FILTRATION.

The results of the chemical analyses, from May to November, inclusive, indicate that on an average 45 per cent. of the total albuminoid ammonia, of which 15 to 20 per cent. is usually in suspension, in the applied river water appeared in the effluents. The total albuminoid ammonia of the river water which appears in the effluents ordinarily ranges from 35 to 60 per cent.; the extremes are 30 and 70 per cent.

A comparison of the efficiency with regard to the removal of organic matter of filtration under different conditions is presented below. For details regarding methods of operation and results of analyses see pages beginning with 488.

*Table showing Per Cent. of Albuminoid Ammonia in Applied Water which appeared in the several Effluents at Different Rates of Filtration.*

[Rates are expressed in million gallons per acre daily.]

In filters of these materials, and in which nitrification is well established, the rate of filtration, within these limits, appears to exert very little or no influence upon the removal of organic matter.

### *Effect of Size of Sand Grain.*

The results obtained in October and November were selected for the following table because they were obtained under comparable conditions.

*I. Continuous Filters.*

| NUMBER OF FILTER. | Effective Size of Sand Grain.<br>—<br>Millimeter. | Average Rate of Filtration.<br>—<br>Million Gallons per Acre Daily. | Per Cent. of Albuminoid Ammonia in Applied Water which Appeared in Effluents. | Per Cent. which Oxygen Consumed in Effluents was of that in Applied Water. |

| 18 A, . . . . . | .48 | 1.7 | 55. | 91. |

In continuous and intermittent filtration, through materials of these limits in effective size and under the given conditions of operation, there was no marked difference in the amounts of organic matter removed from the applied water by the filters which were filled with sand of different effective sizes.

*Effect of Depth of Material.*

There was practically no difference in the power of removal of organic matter from the river water by the several filters of each series. It is to be remembered that in addition to the sand each filter contained 5 inches of underdrains.

In 1892 the results obtained from the first series of filters indicated that the deeper were somewhat more effective than the shallower filters. It is believed that the 1893 data are fairer because they were obtained under strictly comparable conditions.

*Effect of the Method of Application of Water.*

In the Annual Report of the Board for 1892 (page 466) it was shown that there was practically the same amount of free and albuminoid ammonia in the effluents of the continuous and the intermittent filters. The nitrates, however, were higher in the effluents of the latter.

It is to be again stated that it is necessary to consider the different methods practised in running the intermittent filters, and the peculiar features of each. In this connection see page 472.

Nearly all of the samples of effluents of intermittent filters analyzed during 1892 were collected within two or three hours of the time when the effluent began to flow after the interval of rest. The results of the analyses of more extended series of samples collected during different hours of the day in 1893 show that such samples in a majority of cases are not representative with respect to the nitrates in the case of the effluents of intermittent filters under the existing method of operation. The variations are shown by the representative analysis given below of samples from No. 41, taken on September 20. This filter was operated sixteen hours a day with the faucet below always open and untrapped, the rate regulated at the top and the filter allowed to drain during the remaining hours.

While it is seen that there is a marked variation during the day in the nitrates of the effluent of this intermittent filter under these conditions of operation there is, under ordinary circumstances, substantially no change in the effluent of continuous filters. This is

shown by the following table in which are given the average results of three sets of samples collected at 9 A.M. and 3 P.M. from the effluent of No. 33 A the mate of No. 41.

[Parts per 100,000.]

| Hour.           | Color. | AMMONIA. |             | Chlorine. | NITROGEN AS |           | Oxygen Consumed. |
|-----------------|--------|----------|-------------|-----------|-------------|-----------|------------------|
|                 |        | Free.    | Albuminoid. |           | Nitrates.   | Nitrites. |                  |
| 9 A.M., . . . . | .27    | .0017    | .0110       | .20       | .0250       | .0000     | .29              |
| 3 P.M., . . . . | .28    | .0019    | .0110       | .20       | .0250       | .0000     | .31              |

In the table below are given the average results obtained in October and November from the effluent of four pairs of continuous and intermittent filters. The intermittent filters were operated sixteen hours daily, six days in a week, with the outlets untrapped and closed while the filters, after draining, were filled with water from the top. After the air was driven from the pores and the surface covered the outlet gate was opened to give the prescribed rate of flow. Samples were collected at different hours during the day from the effluent of the intermittent filters, and it is believed that the results below, which correspond to the results of the analyses of samples collected four to six hours after the period of rest, are representative for the period.

These results indicate that during these months there was practically no difference in the average chemical purification effected by the continuous and intermittent filters under existing conditions of operation. The most substantial confirmation of this is that Filters Nos. 33 A and 41, a pair which had been operated over a year and a half, contained substantially the same amount of organic nitrogen in the sand on December 8, at the end of the period covered by the analyses presented above. The amount of organic matter in the sand removed by scraping was also the same (see tables, pages 484-486).

During the period of rest (8 hours) in the intermittent filters for the greater part of the year there was increased nitrification of the organic matter stored in the sand; when water was again applied the nitrates formed during the period of rest were gradually washed out, giving a higher quantity for several hours than is found in the effluents of continuous filters. After a time, depending upon the rate of flow, these high nitrates fall to the normal. The reason that the continuous filtration of water is successful, while with sewage this method is a failure, is that the applied water contains dissolved oxygen and, as will be seen from the table (page 482), the dissolved oxygen in the effluents of the continuous filters has never been found wanting. It is to be remembered in this connection that it was shown in the Special Report upon Purification of Sewage and Water, 1890, page 730, that a small amount of oxygen (1 to 3 per cent.) in the air of the filter was effective, provided the air was changed so often that some oxygen was always present at every point.

The results presented above are for the fall months, and it is believed that they are representative for the spring months also. But the evidence at hand indicates that the results are different in the warmest summer weather and in the severest winter weather.

In mid-summer the conditions for nitrification appear to be the most favorable both in continuous and intermittent filters but it is more marked in the case of the latter. This is brought out by the following table of monthly averages of effluents of Filters Nos. 33 A and 41 and by a series of analyses of the effluents. It will be noted that high nitrates in the effluent of the intermittent filter (outlet untrapped and kept wide open) were found when the quantity of effluent yielded after the period of rest exceeded the quantity of water held in the pores of the sand. In the case of the continuous as well as of the intermittent filter the effluent contained at times

more nitrogen than the applied water, showing a removal of organic matter stored in the sand. In most instances the samples from No. 41 were collected at 2 P. M. when series of samples were not taken.

The above results obtained in the warmest weather indicate with regard to nitrification that, under the existing conditions of operation, the advantage lies with the intermittent filters. During the

winter months, with another pair of filters, Nos. 3 B and 8 A, the advantage lay with the continuous filter, as shown by the following table of monthly averages. No. 3 B was operated intermittently, — drained 8 hours daily, outlet untrapped and closed while filling; No. 8 A, continuously. The analyses were made of mixed samples collected in portions at different hours during the day and are believed to be representative.

The differences in nitrification were most marked in January and February and disappeared in March. The reason of this is not yet fully understood, but it is possible that the daily exposure of the surface of No. 3 B where most of the organic matter is stored, to the cold atmosphere and the occasional formation of frost, may have interfered with the bacterial activity necessary for nitrification. It is

significant that series of samples taken at frequent intervals during the day from the effluent of No. 3 B showed no marked variations in amount of nitrates during the cold weather, but in April the series were similar to those obtained from No. 41 on September 20, 1893, and which were presented on page 477.

While considerable light has been obtained upon this subject it is still necessary to have additional data before we can draw final conclusions as to the relative merits of the two methods as well as to the best way of operating a filter intermittently.

### *Dissolved Oxygen in the Effluents.*

In the table below is given the average amount of dissolved oxygen in the applied river water and in the effluents of the several filters. In no case was an absence of oxygen noted in the effluents of continuous filters. The effluents of the intermittent filters contained much more oxygen than did the effluents of continuous filters, and during midsummer the amount was in excess of that in the applied water. The analyses were made about four hours after the expiration of the period of rest in the intermittent filters, and it is probable that the quantity became less as the filter continued in operation.

*Per Cent. which the Oxygen dissolved in the Applied Water and Effluents was of that necessary for Saturation at actual Temperatures.*

## THE REMOVAL OF COLOR FROM WATER BY FILTRATION.

The per cent. of color of the applied water which appeared in the effluents of those filters started in 1892 was shown in the Annual Report for that year to be 55, on an average, after there had been filtered 400,000,000 gallons of water per acre. In 1893, after 800,000,000 gallons per acre had been filtered, the average amount of color in the effluents was 65 per cent. of that in the applied water.

The filter two feet deep (No. 38) was as efficient as those five feet deep.

The filters constructed in 1893 contained sand from Gale's Hill, a different source from that used for the earlier filters. This sand was also used for the Lawrence city filter. While in the earlier filters it was found that the sand was most effective in removing color when new, the sand from Gale's Hill removed practically none at first but gradually acquired this power, although apparently to a somewhat less extent than was possessed by the sand used in 1892 for filling filters.

The mineral analyses of the two sands are as follows:—

No. 38 (1892) sand contained 98.70 per cent. of material insoluble in strong sulphuric acid kept at the boiling temperature for two hours; 0.75 per cent. of alumina; 0.30 per cent. oxide of iron and 0.02 per cent. oxide of manganese.

Gale's Hill (1893) sand contained 97.70 per cent. of material insoluble in strong sulphuric acid kept at the boiling temperature for two hours; 0.96 per cent. of alumina; 0.54 per cent. oxide of iron and 0.13 per cent. oxide of manganese.

# NUMBER OF BACTERIA AND AMOUNT OF NITROGEN FOUND IN THE SAND OF THE SEVERAL WATER FILTERS, DECEMBER 8, 1893.

On this date, after the filters had drained twenty-four hours, numerous samples of sand at different depths were taken from each filter and analyzed chemically and bacterially, with results as follows:—

| NUMBER OF FILTER. | Depth. (Inches.) | Method of Operation. | Length of Time in Operation. | Million Gallons per Acre Filtered to Date. | Average Number of Bacteria in Sand per Gram. | Original Nitrogen in Sand. (Parts per 100,000) | Average Increase of Nitrogen in Sand.* (Parts per 100,000.) |

\* The organic nitrogen was calculated as  $\frac{1}{4}$  of the albuminoid ammonia doubled.

Upon dividing the deep filters into two classes, according to the method of application of water, and summarizing the data, it is found that the intermittent filters contained 108 bacteria per gram and an increase in nitrogen of .0021 part per 100,000 for each million gallons of water filtered per acre; while for the continuous filters these figures become 122 and .0016, respectively. It is probable that somewhat different results would be obtained in mid-summer.

In the next tables the results of the analyses of the sand from the several filters are presented with greater detail. It is to be stated that the method followed until September, 1893, of scraping the filters and not replacing the sand removed, until the depth was decreased 6 to 12 inches, caused greater irregularities than would have been the case if the sand removed had always been replaced with clean material at the time of scraping.

\* Nitrogen in original sand deducted.

Considerable attention was given to the species of bacteria found in the sand at different depths in Filters Nos. 33 A, 41, 44 and 47. No very marked characteristics with respect to the distribution of the species of bacteria could be found in the samples of sand from the different sources. The presence of about fifteen species was noted.

In the following table are given the results of chemical and bacteriological analyses of representative samples of the clogged sand removed from the surfaces of the filters by scraping.

The number of bacteria per gram in these samples was found to be somewhat less than in samples just below the surface, as will be seen from the tables above. The reason of this appears to arise from the difficulty with which the bacteria are detached from the grains which are so thickly coated with the accumulation of gelatinous organic matter. From this it will be understood that the merit of determinations of bacteria in sand lies in their value for comparison and not as absolute determinations.

THE RELATION BETWEEN CONSTRUCTION AND OPERATION OF FILTERS  
AND THE QUANTITY OF SAND SCRAPED FROM THE SURFACES  
TO RELIEVE CLOGGING.

The data obtained in 1893 upon this point are summarized in the table below. These results cover the period May to November, inclusive. As far as can be judged from the analyses of the applied water, it is believed that they are representative for the entire year. The increased viscosity of the water during the winter months, other conditions being equal, would probably reduce somewhat the quantities of water filtered between scrapings.

The depths of sand removed were calculated in each case from the weight of the sand. It will be seen that in the case of those experimental filters having a maximum loss of head of 70 inches the volume of sand removed, per million gallons of water filtered, was in many cases approximately the same.

\* Nos. 35 A and 36 A were complicated by loam layers. No. 37 was scraped but once, and during a portion of the period channels were formed at the sides. For a short time Nos. 36 A and 39 were run intermittently, while No. 35 A was operated continuously for a brief period.

### *Conclusions.*

1. The frequency of scraping increases with the fineness of the material and as the available head decreases.

2. The intermittent filters under the existing methods of operation required scraping less frequently than the continuous filters of the same construction, owing chiefly to a disturbance of the surface sand by the air which is driven from the pores of the filter.

3. These results confirm the conclusions drawn from the studies in 1892, except with regard to the effect of the method of application of water. This discrepancy is doubtless explained by the fact that Filters Nos. 35 A and 41 in 1892 contained, a foot or less from the surface, loam layers, which, together with the method of operation then practised, prevented much air from escaping at the surface.

4. As the filters grow old the sand becomes more compact. This compactness and the accumulation of matter from the water give the effect of a finer material, requiring more frequent scraping. (Filters Nos. 33A and 41 were disturbed to a depth of one foot in July, 1893, while No. 34 A was not treated in this manner.)

### THE WATER TAKEN FROM THE MERRIMACK RIVER AND APPLIED TO THE EXPERIMENTAL FILTERS.

Water taken from the Merrimack River has been applied to all of the water filters, and is brought through a two-inch galvanized iron pipe, about four hundred feet long, from the north canal of the Essex Company. The water is substantially the same as the river water above Lawrence, which is applied to the city filter. The turbidity, sediment and odor are usually very slight, but after heavy rains and during the spring freshets the turbidity and sediment become very marked. The results of analyses are given in the two tables below. In the first table are given the analyses of the water as it was drawn from the pipe. From May 12 until the discontinuance of the experiments, December 8, cultures of *B. prodigiosus*, together with the food on which these germs grew, were applied to the water which supplied the several filters, for ten hours each day. The results of analyses of the water after its inoculation with these germs are given in the second table.

*Monthly Averages of Analyses of Canal Water (Merrimack River).\**

### DETAILED ACCOUNT OF THE WORK OF THE SEVERAL WATER FILTERS IN 1893.

The remaining pages contain a summary of the weekly averages of all bacterial results, followed by a brief description of the operation of each filter and monthly averages of both chemical and bacterial analyses. One bacterial sample was examined daily from each effluent from January until May. These results are more or less abnormal because the conditions existing in the filters were abnormal from time to time. This was caused partly by the formation of channels at the sides of the iron tanks due to freezing weather, and partly to the evolution of air by the water as it increased in temperature, which produced channels within the filters. These conditions were touched upon in the 1892 Report. It is believed that they would not appear in large filters in actual practice. On account of these peculiar and unfavorable circumstances the results obtained from January to May do not appear in the foregoing discussion, and for the same reason the experiments were discontinued during the winter of 1893-94.

#### *General Plan of the Experiments.*

Beginning May 12 *B. prodigiosus* was regularly applied to each filter for ten hours a day on six days in a week. The general plan of the experiments was the same as during the preceding year (see the 1892 Report, page 529). A pure culture of this species of bacteria was obtained by inoculation and growth for four days at 20° C. in a solution of one-tenth per cent. peptone and two-tenths per cent. glucose in city water. This solution was applied to the filters in the proportion of one part to three thousand parts of water, at intervals of one or two hours during the day, according to the rate of filtration. Throughout the experiments four examinations were made daily of each of the effluents, at a time when the water from the applied doses was passing through the outlet-pipes. The reasons that this species of bacteria was used are that it is easy to differentiate from ordinary water bacteria and is apparently very similar to the germ of typhoid fever [of Eberth] in its mode of life in the river water.

The experiments have been conducted with as much uniformity as possible, and the system practised has been substantially the same as that of the preceding year. Notes of the slight changes that have

been made will be found in the proper places. When considering the depths to which the filters were reduced, largely by scraping, it is to be borne in mind that this diminution is partly accounted for by settling. In November most of the filters were filled with water from below (in some cases very rapidly) after scraping, and this, together with the very high rates of filtration, increased the average number of bacteria in the effluents.

In the first table below will be found the results of the mechanical analyses of the sands in the various water filters. The underdrains were 5 inches deep in each case. Filters Nos. 3 B and 8 A are each one two-hundredth of an acre in area and are out of doors. The other water filters are 20 inches in diameter, equivalent to one twenty-thousandth of an acre, and are all placed within the buildings.

The second table beyond contains the weekly averages of the numbers of bacteria in the applied water and in the various effluents. Following this are brief descriptions and monthly averages of the chemical and bacterial analyses of the effluents of the several filters.

The report ends with a detailed account of the results of analyses obtained from the Lawrence city filter and also from the duplicate filters at the Experiment Station, Nos. 3 B and 8 A.

*Mechanical Composition of Materials used for Water Filters in 1893.*

\* Calculated as  $\frac{1}{4}$  of the albuminoid ammonia doubled.

The "effective size" of the sand grains means that ten per cent. by weight of the grains are finer than the diameter given. The "uniformity coefficient" is the ratio A to B when the values of A and B are such that sixty per cent. by weight of the material is finer than A and ten per cent. finer than B. The "maximum rate" is the maximum quantity of water, expressed in million gallons per acre daily, which, at a temperature of 50° F., will pass through a filter of clean sand with no air in its pores, and with no suspended matter upon its surface when the acting head is equal to the depth of sand.

The sand in No. 48 is the same as in No. 49; No. 44 as in Nos. 46 and 47; No. 45 as in Nos. 3 B and 8 A; No. 42 as in Nos. 35 A, 36 A, 37, 38 and 39; and No. 41 the same as in No. 33 A.

The sand in No. 44 corresponds quite closely with the "No. 70" sand in the Lawrence city filter, and No. 45 with "No. 50" sand in the city filter.

Table showing the Number of Bacteria per Cubic Centimeter in the Applied Water and the Effluents from the Various Filters arranged as Weekly Averages of Daily Analyses.

† Filter No. 45 was started July 10, 1893.

## FILTER No. 18 A.

This filter, 20 inches in diameter, contains sand of an effective size of 0.48 millimeter and has been in operation since Sept. 17, 1889. The original depth of the sand was 62 inches. Up to January, 1891, city water was applied in hourly doses, fourteen hours a day on six days a week, at the rate of about one million gallons per acre daily. The faucet at the outlet was always kept wide open until Oct. 1, 1893, and the rate of filtration regulated at the top. The outlet has never been trapped. With the exception of a few scattering days river water taken from the canal has been applied since Aug. 18, 1891. From January, 1891, to July, 1893, the water was applied by an automatic arrangement in small doses equivalent to 5,000 gallons per acre once in three to seven minutes, days, nights and Sundays, according to the rate of filtration. On July 17, 1893, the siphon attachment, by which the water was applied intermittently, was removed and the water applied constantly for sixteen hours a day on six days in a week. Beginning October 1 the faucet at the outlet was closed at 5 A.M. daily after draining over night and the water applied at the top; after the surface was covered the faucet was opened below to give the desired rate of filtration, and the surface was kept covered until the water was shut off at 9 P.M. With the exception of November 21 to 30 this method was followed through the rest of the year.

No sand was scraped from the surface until November, 1892, when it was necessary to remove  $2\frac{1}{2}$  inches in order to keep the action of the filter intermittent. During the four years of its operation the surface was scraped five times and 8 inches of sand were removed without replacement; the water filtered in this time was equivalent to 1,500,000,000 gallons per acre. The sand removed was equivalent to 0.70 cubic yard per million gallons of water filtered. It will be seen that this quantity agrees approximately with some of the results from other filters presented on page 487. On October 9 clean sand was added and the filter restored to its original depth.

\* In all cases the dissolved oxygen is expressed as per cent. of the amount required to saturate the water at the temperature when collected.

## FILTER No. 33 A.

This filter was put in operation April 28, 1892, and contains sand of an effective size of 0.14 millimeter. The original depth was 60 inches. The method of operation has been continuous, except from April 17 to 30, 1893, and for a few days at irregular intervals during the winter, when the filter was accidentally drained, owing to freezing of the water pipes. The rate of filtration has been regulated by the faucet at the outlet, to which a trap is attached. From May 25 to December 8 the filter was scraped 8 times, an average of once in 23 days. The average depth removed at a scraping was 0.23 inch; the average quantity filtered between scrapings was equivalent to 49 million gallons per acre, and the sand removed was equivalent to 0.63 cubic yard per million gallons. On July 17 the upper foot of sand was removed and replaced, as was described on page 465. Until October 6 the sand removed by scraping was not replaced, but on that date the depth was restored from 47 inches to its original depth of 60 inches. After this date the sand was replaced at the time of scraping.

## FILTER NO. 34 A.

This filter contained sand of an effective size of 0.09 millimeter, and its original depth was 60 inches. It was operated continuously after it was first put in operation, April 28, 1892. The rate of filtration was regulated at the outlet by a faucet to which a trap was attached.

From May 12 to September 7, 1893, the date of its discontinuance, the surface was scraped 17 times to relieve clogging. It was scraped on an average once in 7 days. The average depth removed was 0.12 inch; the average quantity of water filtered between scrapings was equivalent to 14 million gallons per acre, and the sand removed was equivalent to 1.16 cubic yards per million gallons. The depth of sand at the date of its discontinuance was 44 inches.

**FILTER NO. 35 A.**

This filter was constructed on March 30, 1892, and contained sand of an effective size of 0.20 millimeter. The original depth was 57.5 inches, and 1 foot below the surface was a layer of loam 1 inch thick. April 17 to 30 and July 31 to September 6, 1893, it was operated continuously with the trap attached to the outlet in the usual manner. During the remainder of the time it was operated intermittently, with the untrapped faucet at the outlet wide open and the rate regulated at the top. The water was applied sixteen hours a day on six days in a week. On July 17, when the layer of loam was less than 3 inches below the surface, the sand was taken out down to the loam, which was removed and the sand replaced.

From May 24 to September 7, the date of its discontinuance, the surface was scraped three times to relieve clogging, and the average depth removed was 0.25 inch. The average quantity of water filtered between scrapings was equivalent to 92 million gallons per acre. It was scraped on an average once in 33 days, and the sand removed was equivalent to 0.36 cubic yard per million gallons.

The depth of the sand on September 7 was 49 inches.

**FILTER NO. 36 A.**

This filter was constructed on the same date and in the same manner as No. 35 A. It was operated continuously, except from April 17 to 30 and from July 31 to September 7, when it was operated intermittently in the same manner as No. 35 A.

From May 12 to September 7, 1893, the date of its discontinuance, the surface was scraped 7 times to relieve clogging, and the average depth removed was 0.21 inch. The average quantity of water filtered between scrapings was equivalent to 35 million gallons per acre. It was scraped on an average once in 14 days, and the sand removed was equivalent to 0.82 cubic yard per million gallons.

The depth of sand on September 6 was 48 inches.

FILTER No. 37.

This filter was constructed on April 18, 1892, and contained originally 61 inches in depth of sand having an effective size of 0.20 millimeter. It was operated continuously until June 25, 1893, when the experiment was discontinued, owing to an accident which happened to the tank.

The results obtained from this filter are more or less affected by evolution of air from the water and the formation of channels at the sides of the iron tank, as is indicated by the results of the analyses below and by the fact that this filter of medium fine sand was operated for more than three months during the winter without scraping. It was scraped on June 19 to relieve clogging, and 0.20 inch was removed. The depth of sand on this date was 55 inches.

FILTER No. 38.

This filter contained sand of an effective size of 0.20 millimeter, and its original depth was 24 inches. The date of its construction was April 28, 1892. It has been operated continuously in the usual manner.

From May 25 to December 4 the surface was scraped 18 times to relieve clogging. It was scraped on an average once in 11 days. The average depth removed was 0.17 inch; the average quantity of water filtered between scrapings was equivalent to 22 million gal-

lons per acre, and the sand removed was equivalent to 1.06 cubic yards per million gallons.

The sand removed by scraping was not replaced with clean material until Sept. 12, 1893. The depth of sand was about 14 inches on that date, when the filter was refilled to its original depth. From this time on the sand was replaced at the time of scraping. The addition of new sand in September caused a greater (percentage) removal of color.

**FILTER No. 39.**

The filter contained sand of an effective size of 0.20 millimeter. Its depth on the date of its construction, April 28, 1892, was 12 inches. It was operated continuously up to Aug. 19, 1893, the date of its discontinuance, with the exception of July 10 to 30, when it was operated intermittently with the outlet untrapped and wide open. The depth of sand May 1, 1893, was 2.5 inches. From May 12 to August 19 the surface was scraped 14 times to relieve clogging, and the average depth removed was 0.15 inch. The average quantity of water filtered between scrapings was equivalent to 13 million gal-

lons per acre. It was scraped on an average once in 7 days, and the sand removed was equivalent to 1.55 cubic yards per million gallons.

The depth of sand in the filter at the time the experiment was brought to an end was about 0.5 inch. In addition to this, however, there were 5 inches of underdrains, some of the material of which was fairly fine.

**FILTER No. 41.**

This filter, a duplicate of No. 33 A, was constructed May 9, 1892, and contained originally 60 inches in depth of sand of an effective size of 0.14 millimeter. It has been operated intermittently, except from April 17 to 30, with the outlet untrapped. On July 17 the upper foot of material was dug out and put back (see page 465). Up to Oct. 1, 1893, the faucet at the outlet was kept wide open and the rate of filtration regulated at the top. During the rest of the year, except November 21 to 30, it was operated as follows: the faucet at the outlet was closed at 5 A.M. daily, after the filter had been allowed to drain over night, and the water applied at the top; after the surface was covered the faucet was opened at the outlet to give the desired rate of filtration, and the surface was kept covered until the water was shut off at 9 P.M.

From May 12 to December 8 the surface was scraped 8 times to

relieve clogging, — an average of once in 22 days. The average depth removed at a scraping was 0.19 inch; the average quantity of water filtered between scrapings was equivalent to 56 million gallons per acre; and the sand removed was equivalent to 0.46 cubic yard per million gallons.

Until Nov. 15, 1893, the sand removed by scraping was not replaced with new material, but on that date the depth was restored from 52 inches to its original depth of 60 inches. After this date the sand was replaced at the time of scraping.

**FILTER NO. 42.**

This filter was started on Oct. 29, 1892, and contained 13 inches in depth of sand of an effective size of 0.20 millimeter. It has been operated continuously in the usual manner. The depth of sand in May, 1893, was 10 inches.

From May 12 to December 8 the surface was scraped 24 times to relieve clogging. It was scraped on an average once in 7 days. The average depth removed was 0.16 inch; the average quantity of water filtered between scrapings was equivalent to 19 million gal-

lons per acre; and the sand removed was equivalent to 1.11 cubic yards per million gallons.

The sand removed by scraping was not replaced with clean material until September 9. The depth of sand was then about 7 inches, and the filter was refilled to its original depth. From this time on the sand was replaced at the time of scraping. The addition of new material in September caused a greater (percentage) removal of color.

**FILTER No. 43.**

This filter was started on May 20, 1893, and contained 60 inches in depth of sand of an effective size of 0.26 millimeter. It has been operated continuously.

From May 20 to December 8 it was scraped 16 times. This was an average of once in 10 days. The average depth removed was 0.26 inch, and the average quantity of water filtered between scrapings was equivalent to 57 million gallons per acre. The sand removed was equivalent to 0.63 cubic yard per million gallons.

The sand removed up to October 13 was replaced with clean material on that date, and after that time the sand was replaced at the time of scraping.

## FILTER NO. 44.

This filter was put in operation, continuously, May 20, 1893, and contained 60 inches in depth of sand of an effective size of 0.29 millimeter. The sand removed by scraping up to October 27 was replaced on that date, and after that time the sand was replaced with clean material at the time of its removal.

From May 20 to December 8 the surface was scraped 13 times to relieve clogging, and the average depth removed was 0.30 inch. The average quantity of water filtered between scrapings was equivalent to 70 million gallons per acre. It was scraped on an average once in 13 days, and the sand removed was equivalent to 0.58 cubic yard per million gallons.

## FILTER No. 45.

This filter was constructed July 10, 1893, and contained 60 inches in depth of sand of an effective size of 0.23 millimeter. It has been operated intermittently after the same method that was used in the case of No. 41 (see page 503). With respect to size of sand grains it resembles most closely the continuous filter No. 43.

From July 10 to December 8 the surface was scraped 4 times. This was an average of once in 35 days. The average depth removed was 0.28 inch, and the average quantity of water filtered between scrapings was equivalent to 78 million gallons per acre. The sand removed was equivalent to 0.48 cubic yards per million gallons.

The sand removed up to October 27 was replaced with clean material on that date, and after that time the sand was replaced at the time of scraping.

## FILTER No. 46.

This filter was put in operation Aug. 21, 1893, and contained 12 inches of sand of an effective size of 0.29 millimeter. This sand was from the same lot as that used for No. 44. It has been operated continuously. From August 21 to December 8 the surface was scraped 9 times to relieve clogging, and the average depth removed was 0.25 inch. The average quantity of water filtered between scrapings was equivalent to 29 million gallons per acre. It was scraped on an average once in 11 days, and the sand removed was equivalent to 1.16 cubic yards per million gallons.

## FILTER No. 47.

This filter was put in operation Sept. 8, 1893, and contained 60 inches in depth of sand of an effective size of 0.29 millimeter. The sand was of the same size and from the same lot as that of No. 44. It has been operated intermittently in the same manner as No. 41 (see page 503).

From September 8 to December 8 it was scraped twice, an average of once in 42 days. The average depth removed was 0.45 inch, and the average quantity of water filtered between scrapings was equivalent to 100 million gallons per acre. The sand removed was equivalent to 0.60 cubic yard per million gallons.

## FILTER No. 48.

This filter was put in operation Sept. 9, 1893, and contained 60 inches in depth of sand of an effective size of 0.38 millimeter. It has been operated intermittently in the same way as No. 41 (see page 503).

Up to December 8 it was scraped but once, — 71 days after it was first put in operation. The depth removed was 0.88 inch, which was equivalent to 0.66 cubic yard per million gallons of water. The quantity filtered up to the time of the scraping was equivalent to 181 million gallons per acre.

## FILTER No. 49.

This filter, a duplicate of No. 48, was put in operation Sept. 9, 1893. It has been operated continuously. Up to December 8 the surface was scraped 4 times, an average of once in 37 days. The average depth removed was 0.32 inch, and the average quantity of water filtered between scrapings was equivalent to 79 million gallons per acre. The sand removed was equivalent to 0.53 cubic yard per million gallons.

## FILTERS NOS. 3 B AND 8 A.

These filters are each one two-hundredth of an acre in area, and contain 5 feet in depth of sand of an effective size of 0.23 millimeter. This sand was taken from the same place as that which was used in the construction of the Lawrence city filter, and in size it is very similar to a large proportion of the sand in the city filter. The maximum rate at which this sand will allow water to pass, when the acting head is equal to the depth of the sand, is estimated at 43,000,000 gallons per acre daily. The maximum loss of head in the case of each filter is about 73 inches.

Filter No. 3 B has been operated intermittently since Sept. 23, 1893, as follows: at 5 A.M. the gate on the outlet pipe, to which no trap has been attached, was closed, and the water turned on at the top, near the edge. When the filter was covered (about 7.30 A.M.) the gate on the outlet pipe was opened to give the prescribed rate of filtration, and the surface was kept covered until 9 P.M., when the water was shut off and the filter allowed to drain during the night. The filter has been operated in this manner six days in a week, and allowed to rest, after draining, on the seventh day. The rate of flow was 10 gallons per minute for about 16 hours during the day. This rate is equivalent to 2,880,000 gallons per acre daily (24 hours). In addition to the quantity of effluent obtained at this rate for 16 hours daily there is the daily drainage of the water held in the pores of the sand, equivalent to about 400,000 gallons per acre. On Feb. 27, 1894, the rate was reduced from 10 to 8 gallons per minute, owing to a lack of water supplied by the inlet pipe. The total

quantity of effluent yielded up to May 1, 1894, was equivalent to 356,191,100 gallons per acre, which is an average daily rate of 1,650,000 gallons per acre, or 1,925,000 gallons for each of the six days weekly on which it was actually operated. The first occasion on which the filter failed to yield water at the prescribed rate was on December 19, when the total quantity of effluent was equivalent to 153,105,500 gallons per acre. The outlet gate was closed, with the surface covered, from 9.25 to 10.25 A.M., during which time the air that had been held in the pores of the sand bubbled up through the surface and caused the water level to drop 5 inches. This treatment was repeated on Dec. 24, 1893, Jan. 13, 15, 16 and 17, 1894. Ice was removed from the surface, in order to facilitate the displacement of air by water within the filter, as follows: January 4, 2 to 8 inches; January 16, 4 inches; February 26, 6 inches. The ice was broken along the edges on January 15, when it was 6 inches thick. The filter was drained every night, and from 1 to 3 inches of frost frequently appeared at the surface and caused an unfavorable effect upon the removal of bacteria and upon nitrification during the winter months (see pages 468 and 481). On Jan. 31, 1894, a wooden conduit, similar to the lateral conduits at the Lawrence city filter, was placed across the middle of the surface to aid in the distribution of the water. The filter was scraped about 0.6 of an inch deep on March 17, 1894, and the surface ridged; the depth of sand at the sides, at right angles to the conduit, was increased 6 inches, and the surface graded off toward the centre, somewhat similar to the arrangement of the surface of the Lawrence city filter. It was not necessary to scrape the surface at this time to relieve clogging, as the loss of head was only 18.5 inches on this date. The total quantity of effluent up to this time was equivalent to 295,226,500 gallons per acre. The discolored and partially clogged sand removed was equal to 0.27 cubic yard per million gallons. The reason that this filter yielded so much more water without scraping than No. 8 A, its continuous mate, was that the method of operation practised caused a disturbance of the accumulating sediment on the surface. The effect of this was also felt in the bacterial results, as will be seen beyond.

In the tables on the pages beyond are presented the daily results obtained from Filters Nos. 3 B and 8 A, and in the foot-notes mention is made of all special features in the operation of the filters.

Filter No. 8 A has been operated continuously since September 26 at the rate of 7 gallons per minute, equivalent to 2,016,000 gal-

lons per acre daily. The rate of filtration, which is controlled by a gate on the outlet pipe to which no trap was attached, was reduced on February 27 to 5 gallons per minute, owing to a reduction in the quantity of water delivered by the inlet pipe. The total quantity of effluent yielded up to May 1, 1894, was equivalent to 359,850,300 gallons per acre, which is an average daily rate of 1,660,000 gallons per acre. During this period the surface was scraped six times, as follows: October 24, November 13, December 2, February 21, March 17 and April 23. The depth removed in each case was about 0.3 of an inch, which is equivalent to 0.70 cubic yard per million gallons on an average. The average quantity of water yielded between scrapings to relieve clogging was 58,200,000 gallons per acre; the minimum, 36,900,000 gallons; and the maximum, 147,600,000 gallons per acre. The average number of days between scrapings was 35, the minimum 19 and the maximum 81. During the latter period (December 2 to February 21) the filter became clogged seven times, as follows: December 29, January 16, 26 and 29, February 10, 12 and 19. On each occasion the prescribed quantity of water failed to pass through the filter with the gate on the outlet pipe wide open. The pores of the sand at these times contained considerable air; how much of it was evolved by the water is not definitely known, but it appears now that the greater part came through the untrapped outlet pipe, which was only partly filled with water on these days. By shutting the gate on the outlet pipe the air rose to the surface and disturbed the layer of accumulated sediment sufficiently to allow filtration to proceed for some days. To facilitate the displacement of air within the pores by water the ice was removed as follows: December 29, 3 to 8 inches; January 16, 2 to 8.5 inches; January 29, 6 inches; February 12, 3 to 6.5 inches; February 21, 2 to 6 inches. The ice was broken along the edge on February 10 and 19. The space above the top of the sand was 9 inches. It is probable that scraping could have been considerably longer postponed by continuing this method of treatment. The filter was scraped on March 17 for the sake of getting conditions for experiments comparable with those in No. 3 B. The filter was not clogged on that date. Neither filter was at any time protected from the weather.

The monthly averages of the results of chemical and bacterial analyses, which have already been discussed, are presented in the following tables:—

*Monthly Averages of Analyses of Merrimack River Water taken from the Canal and applied to Filters Nos. 3 B and 8 A.*

The treatment of this filter on March 17, 1894, by which the surface was ridged in the manner already described, appeared to lessen the mechanical disturbance of the sand during the process of filling

the filter from the top, and thereby increase its bacterial efficiency. The average of the results given above show that during the period November to April, inclusive, this filter allowed 2.13 per cent. of the number of applied bacteria to pass through into the effluent. These results, however, cover only the first eight hours of each day's flow, and it has been learned that during the latter half of the flow (4 P.M. to midnight) the efficiency is practically the same or a very little greater than at 4 P.M. Averaging then the results obtained at 4 P.M. with the total average for the first half of the day (8 A.M. to 4 P.M.) we find that 1.93 per cent. of the number of applied bacteria passed through, — a removal of 98.07 per cent.

*Monthly Averages of Bacterial Results from (Continuous) Filter No. 8 A.*

| Average per cent. in effluent of number applied, |                                                                         | -                                                           | 0.88                                          | 0.88    | 0.92   | 0.95   |

Experiments upon this filter show that, under normal conditions, its efficiency in removing bacteria is substantially the same during the entire twenty-four hours. The averages given above include all results obtained and indicate that in some cases somewhat variable numbers were found in the effluent during the day. This is explained by the existence of some abnormal condition during a very few days in the month. The average results for the period, November to April, inclusive, show that the effluent contained 0.91 per cent. of the number of applied bacteria, — a removal of 99.09 per cent.

*Filter No. 3 B (Intermittent).*

The total quantity of effluent to the end of October was 63,200,400 gallons per acre.

The gate on the outlet pipe was closed October 7, 4 P.M., to October 9, 8 A.M.; and October 23, 8.40 to 11.35 A.M. On October 24 the surface was allowed to uncover, and was scraped between 10 and 12 A.M.

Quantity of effluent for month was 53,275,300 gallons per acre.

To remove the air held in the pores of the sand and which prevented a normal flow of water the outlet was closed December 19, 9.25 to 10.25 A.M., and December 24, 9.45 to 11 A.M.

Quantity of effluent for month was 60,958,800 gallons per acre.

The surface was scraped on December 2 between 10 A.M. and 4 P.M. The loss of head was equal to the depth of the filter on December 29; the ice 3 to 8 inches in thickness was removed and the outlet closed 8.30 to 11.45 A.M. to allow the escape of air held in the sand.

*Filter No. 3 B (Intermittent) — Continued.*

Quantity of effluent for month was 49,358,000 gallons per acre.

January 4, 2 to 8 inches of ice removed. January 13, outlet closed 10.45 A.M. to 2.50 P.M. January 15, ice 6 inches thick was broken along the edge and outlet closed until 3.50 P.M. January 16, 4 inches of ice removed and outlet closed 10 to 11.15 A.M. January 17, outlet opened at 10.30 A.M.; a large quantity of air appeared at the surface. January 31, a wooden distributing trough put on surface.

Quantity of effluent for month was 40,731,400 gallons per acre.

February 1, the filter was not drained on the night preceding. February 24, the filter was filled from below with city filtered water. February 26, 6 inches of ice removed; 1 to 2.5 inches of frost in sand; filled with city-filtered water from below (rate, 1,150,000 gallons per acre daily) and allowed to stand over night. February 27, rate reduced from 10 to 8 gallons per minute.

*Filter No. 8 A (Continuous)* — Continued.

Quantity of effluent for month was 40,765,200 gallons per acre.

February 6, inlet pipe frozen and surface uncovered. February 10, ice 4 inches thick broken along the sides and outlet closed 7.55 A.M. to 3.45 P.M. February 12, ice 3 to 6.5 inches thick removed and outlet closed 8 A.M. to 1.40 P.M. February 19, ice 4 inches thick broken along the sides and outlet closed 8.30 A.M. to February 20, 8 A.M. February 21, 2 to 6 inches ice removed and surface scraped. After filling, filter was allowed to stand with outlet closed from 9 P.M. till 8 A.M. the next morning. February 24, inlet pipe frozen and surface uncovered. February 15, filter allowed to drain. February 26, filled with city filtered water from below and allowed to stand over night with outlet closed. February 27, rate reduced from 7 to 5 gallons per minute.

*Filter No. 3 B (Intermittent) — Continued.*

Quantity of effluent for month was 45,960,400 gallons per acre.

March 4 and 11, filter filled with city filtered water from below and allowed to stand over night. March 17, surface scraped and new sand added to ridge the surface similar to that of the Lawrence city filter; the sand at the sides at right angles to the wooden conduit was made 6 inches deeper than in the middle, towards which it was graded. The filter was filled from below with city filtered water on the night of March 18. The filter was filled as usual, from the top, on March 25, and allowed to stand over night with the outlet closed.

*Filter No. 8 A (Continuous) — Continued.*

Quantity of effluent for month was 39,995,200 gallons per acre.

The filter was allowed to drain March 4, 11 and 17; and was filled with city filtered water from below March 5, 12 and 19, and put in operation in the usual manner as soon as the surface was covered. The surface was scraped on March 17.

*Filter No. 3 B (Intermittent) — Concluded.*

Quantity of effluent for month was 40,926,400 gallons per acre.

The filter was filled from the top in the usual way on April 1, 8, 15, 22 and 29, and allowed to stand over night with the outlet closed. The outlet was closed and the surface remained covered on the night of April 23.

*Filter No. 8 A (Continuous)*—Concluded.

Quantity of effluent for month was 41,141,500 gallons per acre.  
The surface was scraped on April 23.

## LAWRENCE CITY FILTER.

This filter was first put in use Sept. 20, 1893. The construction and operation of the filter are fully described in an article beyond by its designer, Mr. Hiram F. Mills, A.M., C.E., chairman of the committee on water supply and sewerage of the State Board of Health. Briefly, it is 2.5 acres in area; the underdrains conduct the effluent to a collecting conduit and thence to the pump well. The nominal capacity of the pumps is 5,000,000 gallons in 24 hours, and when pumping at this rate water passes through the filter at a rate of 2,000,000 gallons per acre in 24 hours. The average daily consumption is a little over 3,000,000 gallons, and the pumps work on an average about 16 hours; under ordinary circumstances, the surface of the filter is uncovered and the sand drained about 8 hours daily. The effluent is pumped to the open distributing reservoir, which is 25 feet deep at the high-water mark and has a capacity of 40,000,000 gallons.

Very frequent analyses, both chemical and bacterial, have been made of the Merrimack River water before and after its passage through the filter, as it leaves the reservoir, and from taps at the City Hall and Experiment Station, which are distant about 1.5 and 2.5 miles, respectively, from the reservoir. A summary of the results of these analyses is presented below.

*Monthly Averages of the Analyses of the Merrimack River Water as it flows on to the Lawrence City Filter.*

| Average per cent. of number of river bacteria remaining in water, . . . . . | -                                           | 2.42                | 1.27              | 0.83           | 0.75                    |

In the table above all results are included in the averages. Some of these results were obtained under abnormal conditions, and in the table below are presented averages from which are excluded the results from October 1 to 17, which were obtained before the filter arrived at its normal efficiency; those of November 27, 28 and December 4, when high numbers were present in the effluent, which were doubtless caused by lowering the suction pipe in the pump well and thereby disturbing the sediment which had collected there before the filter was put in use; and the results from February 20 to March 12 when the water passed through a very limited area of the filter.

These results show that during this period the normal efficiency of this filter in the removal of bacteria was 98.33 per cent. of the number applied.

In the next table are given the results of the bacterial examination of series of samples of the effluent of the city filter taken at different hours during the day. The pumps were started between 7 and 7.30 A.M. All things taken into consideration, the results are quite uniform under ordinary circumstances. Both the bacterial and the chemical analyses indicate that some ground water at times is mixed with the effluent.

Total quantity of effluent for month, 85,279,992 gallons.

On February 19 there were about 2 feet of ice on the surface, and in places on the side opposite from the main distributing conduit it was frozen to the sand considerable air was in the pores of the sand. During the next 10 days a strip about 6 feet in width was scraped along each lateral conduit for about two-thirds the width of the filter.

Total quantity of effluent for month, 88,132,232 gallons.

The ice had disappeared by March 12 and the surface was gradually scraped and graded. This took about a month, and was the third complete scraping of the surface.

*Daily Bacterial Results, Lawrence City Water — Concluded.*

[Bacteria per cubic centimeter.]

MEMBER OF THE STATE BOARD OF HEALTH OF MASSACHUSETTS.

---

The Lawrence pumping station is by the side of the Merrimack River above the city and about a thousand feet up stream from the nearest house. The water was drawn from the river through a thirty-inch iron pipe continued to the engine house by a brick conduit four feet in diameter. At right angles with this conduit, and extending down stream from the engine house for three hundred feet along the shore, was a stone and brick filter-gallery eight feet wide and eight feet high inside, the bottom of which, as well as the bottom of the conduit from the river, was about level with the bottom of the pump well under the engine house and eleven feet below low water in the river.

The river water brought so much silt at the time of the spring and fall freshets that the shore became impermeable, and soon after the works were constructed it became evident that the filter-gallery received little or no water from the river side and the quantity received from the land side was insignificant. The works have been in use about seventeen years. For some years after they were built there was a diminution in the number of deaths by typhoid fever from the number when well water was used, and no one thought of direct poisoning by sewage of the water taken from the river nine miles below Lowell with a fall of ten feet through a rapid a mile long on the way. Many made the remark that running water purified itself in a less distance and put away any fear of contamination, while a few did not like to drink water into which the sewage of seventy thousand people was poured only eight hours before it reached the intake of the water works.

Shortly after the State Board of Health was reorganized in 1886 the Experiment Station was established at Lawrence, and it was soon found that all of the bacteria in sewage, amounting generally to

several hundred thousand in every thimbleful, could be removed by slow intermittent filtration; also, that the same result could be attained by filtering water at a more rapid rate, but not at a rate that rendered it practicable to apply to a city's water supply. Experiments of the Board with rapid mechanical filters showed a large percentage of the bacteria remaining in the filtered water, and experiments at Berlin indicated that the continuous filters of that city allowed some of the germs of typhoid fever to pass through; enough to cause sickness in the city.

In 1890 a careful study of the deaths from typhoid fever in the cities of the State showed that the cities of Lowell and Lawrence had nearly three times the average number, from the same population, in other cities; and that during the season — August, September and October — when other cities had the most typhoid fever, Lowell and Lawrence had about the same number as other cities, but a month or more later the deaths in Lowell reached three and four and eight times the deaths in other cities, and after another month those of Lawrence increased by a still greater ratio, so that in some years the deaths in January and February from this disease were more than the actual number in Boston, with ten times the population. This condition, following year after year, made it so evident that the disease came down the river to Lowell from the cities and towns above, and then came with greater intensity from Lowell to Lawrence, that the State Board of Health made strenuous efforts to produce a filter that would remove all disease-producing germs that could be applied to it, and at the same time filter rapidly enough to serve for a city's water supply. Billions of typhoid-fever germs were cultivated and applied to filters of different construction, and in 1891 we succeeded in removing all that were applied when filtering two million gallons per acre daily. Then the Board advised the city of Lawrence to filter its water, and offered to show how to do it.

Such a filter would require some layers of quite fine sand, and it was thought necessary to first take out the very fine river silt from the water by means of a coarser sand filter at the river bank. Further experiments showed that the construction of a filter at the river bank with a sand coarse enough to allow the river silt to be deposited upon it, if removed promptly, would serve to remove ninety-eight per cent. of all of the bacteria of the river water and a still larger per cent. of the disease producing germs; and considera-

tions of economy and the immense advantage of such a filter with the probability of this or none, with an unbelieving public, induced the State Board of Health to advise the city to immediately construct such a filter and save the fifty-seven lives, which was the annual excess of deaths by this disease over that of the same number of inhabitants in cities of the State having a good water supply.

In 1892, in view of the possibility of cholera getting into Lowell and making it necessary to cut off the Lawrence water supply, the city government made an appropriation for beginning the work of constructing the filter in accordance with the advice of the State Board of Health and under its direction.

The general design was to excavate the bed and bank of the river to seven feet below low water for a width of about one hundred and fifty feet out from the old filter-gallery and from the high water shore down stream from this, making a length of about seven hundred and fifty feet and an area of excavation of two and one-half acres (see Plate I., Fig. 7). The suitable material from the excavation was to be put into a tight embankment, on the ends and river side, carried to nine feet above low water in the river or high enough to exclude the highest freshets. The excavation was to be then filled for a depth of about five feet with suitable filtering sand properly underdrained into the old filter-gallery and into a small perforated conduit in extension of the gallery.

The top of the sand, being two feet below low water in the river, could by a proper inlet be flooded by gravity to a depth of about two feet, thus forming a shallow pond of two and a half acres area, which would gradually filter downward through the sand to the underdrains and be conveyed to the old gallery, and through this to the pump-well.

One of the essential qualities of the design required that the inlet water should be shut off once a day and the pumps kept running until the sand was uncovered and the water within the sand drawn out, so that the sand could fill with air from top to bottom.

This condition of filling the sand with air daily was regarded necessary to insure the burning up of the organic matter which penetrated the sand below the surface and forming nitrates in the water, thus producing conditions the most unfavorable for the continuation of the life of bacteria within the water in their passage through the sand and in the water after leaving the filter.

There is nearly air enough in our drinking waters to supply the

oxygen which is necessary to carry on the process of nitrification when the water comes in contact with the grains of sand which have nitrifying bacteria adherent, but the addition of the air which enters the sand by drawing the water out of it once a day causes a more complete burning up of the organic matter in the water, which is the nitrifying process spoken of.

The question may arise, if water contains so much air why does not nitrification take place in the reservoir? The reason is that nitrification will not take place unless the water with the air comes in contact with certain bacteria which in some unknown way cause the process to be carried on. These bacteria attach themselves to the grains of sand of the filter and remain there, and when air is present they can in a short time cause the nitrifying process to be carried on so completely that nearly all of the organic matter in the water is burnt up, and with this burning the disease germs in the water are killed.

The carrying out of this design required some original investigations upon the head required to convey a definite quantity of water through sands of different size of grain and through gravel stones of different sizes. The circumstances of the location would allow an expenditure of head of one and a half feet when the surface of the sand was clean, through the sand and through the underdrains and conduit to the pump-well, when drawing the full quantity of 2,000,000 gallons per acre per day, or 5,000,000 gallons for the field.

The sand selected to meet these conditions was of two sizes, the finer of the two being placed directly over the underdrains and for five feet each side of them; and the coarser occupying the remaining twenty feet between the drains, and through which the water would move laterally and use up about the same amount of head as when flowing directly downward through the finer sand.

The coarser sand was such that 70,000,000 gallons would flow in twenty-four hours through a foot in depth, covering an acre, with the expenditure of one foot head; and the finer sand would convey 50,000,000 gallons under the same conditions. In moving vertically downward five feet through the finer sand, 10,000,000 gallons would flow through with the expenditure of one foot of head, but the water moving laterally through the coarser sand toward the underdrain would crowd the stream in the finer sand below the surface so that the water going through the surface in a width of ten feet would

be, near the bottom, pressed into a channel of perhaps not more than five feet in width and thus decreasing the quantity that could pass with one foot head to perhaps 7,000,000 gallons per acre per day.

As the water was to flow through the sand with a daily intermission of several hours, the actual time of flowing would be, say two-thirds of the day, and would allow between four and five millions to pass. This is the quantity that could pass with one foot loss of head through the sand when the surface of the sand is clean, but the fine mineral sediment and the organic matter brought by the river water choke the surface and reduce the quantity of water that can pass through, and in order not to have to clean the surface too frequently, the sand when clean should be able to convey two or three times the quantity required.

It was expected, from experiments that had been made with this water, that ordinarily with sand grains of the sizes here used, the surface would have to be cleaned by removing from an eighth to a quarter of an inch and replacing with clean sand once a month, and that during freshets, when more sediment comes in the river water, the surface would have to be cleaned oftener.

If the surface should not be cleaned as often as necessary, the result would be a lowering of water in the pump-well and if neglected until the surface became so impervious that the one or two feet in depth of water over the surface were not sufficient to force the required quantity through the upper layer, the drawing down of the pump well to the bottom of the sand would give no relief, the surface would have to be cleaned.

Economy of construction, the providing for a nearly uniform rate of filtration through every square foot of the area of the filter, and applying the water to the surface of the sand in a valley so that as it is filled daily there will not be a current over the surface of the sand sufficiently rapid to move the sand grains, caused the following section to be adopted.

The underdrains were arranged to be thirty feet apart. The excavation was not made to a uniform depth of seven feet below low water in the river, but was made to the depth of eight feet for a width of five feet where the underdrains were to be, and to the depth of six feet for a width of five feet at ridges between the underdrains, with slopes of one foot in ten feet between (see Plate I., Figs. 3, 4, 5 and 6). Over these ridges the sand was filled only to the depth of three feet for a width of five feet and beyond this the surface of the

sand rose one foot in twenty feet and then ran level for five feet at a height of six feet above the bottom. Such ridges and hollows formed the general longitudinal section of the bed.

The direct conduit through which water was formerly supplied to the pump-well from the river is at the up-river end of the filter-bed (Plate I., Fig. 1). It is furnished with a gate at the inner end, and the top was pierced and a chimney built about forty feet outside of the engine house, and projecting through the side of this chimney were set two iron pipes two feet in diameter with a gate in each, having its centre two feet below low water in the river. One of these is intended to supply an extension of the works up the river; the other discharges into an open conduit which extends along the inside of the embankment nearly the whole length of the bed. At the upper end the section is a semi-circle six feet in diameter. The edge toward the bed remains level throughout its length at three feet below low water of the river, but the bottom rises gradually from three feet below the edge to six inches below at the lower end, and this continues by a curve and crosses the bed in the down-river valley with the edges level, but the bottom rises so that the depth at the end is only one inch. In each of the valleys, thirty feet apart, extends from this main conduit a shallow carrier of concrete lined with cement mortar, having its edges level with the edge of the conduit, and extending from the conduit to thirty-two feet from the opposite side of the bed. These are two feet wide and three inches deep at the conduit, and one foot wide and one inch deep at the end. In this way there are formed edges of water carriers at the same level and about one and one-third miles in length, over which the water reaches the sand, and as within two feet from these edges the surface of the sand rises with a slope one foot in ten there is very little perceptible current over the sand as the water leaves the carriers.

The conduit is made of cobble paving stones four to six inches through, laid in Portland cement mortar on a layer of gravel eight inches thick and made smooth within by a coat of mortar. The carriers are made of cobble stones about four inches in diameter, laid in Portland cement mortar on the sand, and made smooth within. At the junction with the conduit the carriers are widened by curves to prevent washing of sand at the turn.

The underdrains enter the old filter-gallery through holes cut in the wall. (See Plate I., Fig. 2.) Glazed sewer pipe surrounded by stones are used for about four-tenths of the distance from the

gallery across the bed, beyond which are layers of stones of different sizes without pipes. Beginning at the gallery is one length of ten-inch pipe, then two lengths of eight-inch pipe, then from thirty-five to sixty-five feet of six-inch pipe, ending with three lengths of four-inch pipe. These pipes are laid apart so that the spigot approaches but does not enter the bell, and they are surrounded by a layer of about four inches of stones about two inches in diameter. (See Plate I., Figs. 3, 4, 5 and 6.) Other layers, decreasing in size through one and one-half inches, three-quarters of an inch, three-eighths of an inch and three-sixteenths of an inch, are applied in the form shown by the sections and plans, and the latter being spread out to a width of seventeen feet is covered by one inch of coarse mortar sand which spreads to a width of twenty feet. Upon this rests the filtering sand from four to five feet deep.

The valley in the excavation is deepened in the part occupied by the pipe so that the pipe has a slope of one foot in one hundred feet. The pipe was applied as far from the filter-gallery, or conduit in extension of the gallery, as it and the stones surrounding it cost less than the much larger area of stones required to give the desired freedom of flow. Beyond this the large stones were spread out to the widths and with the depths required to give the desired flow.

To determine how much head would be used in flowing through layers of sand and layers of stones of different sizes experiments were made under my direction by Mr. Allen Hazen, the chemist in charge of the Experiment Station of the State Board of Health. As is well known, the head required to convey water through ordinary pipes varies with the square of the velocity, but with extremely small pipes and through the interstices of fine sand the head required to convey water varies with the velocity and with the temperature, more head being required with colder water. Through coarse sand and through gravel stones the head varies with powers of the velocity between the first and second powers, increasing with the size of the grains or of the stones. For sands, ten per cent. of whose grains are as small as two millimeters or eight-hundredths of an inch in diameter, the quantities of water that would pass through an acre in area with different depths and sizes of grains were determined by the following formula deduced from experiments which had been made up to the time of constructing this filter:  $Q = \frac{800}{l} h^{1.42}$  in which  $Q$  expresses the quantity of water in million gallons per acre per day,  $h$  the acting head in feet,  $l$  the distance flowing through the sand in

feet, and  $d$  the maximum diameter in millimeters of the finer ten per cent. of the sand grains.

This formula expresses quite satisfactorily the quantity of water that will pass through clean sand from which air has been pushed out when the temperature is about 50° Fah., and is convenient to use in comparing sands of different sizes; but Mr. Hazen found that the resistance was nearly twice as great when the temperature was near the freezing point as when at summer heat, and he afterward determined an expression from the experiments, giving the velocity of flow through sands at any temperature, which may be found on page 553 of the Report of the State Board of Health for 1892.

The sand used in the Lawrence filter which was placed directly over the underdrains and five feet on either side had the coarser grains of the finer ten per cent. twenty-five hundredths of a millimeter in diameter, and by the above formula when the head used is equal to the distance which the water passes through the sand the quantity of water that could pass through an acre in twenty-four hours would be fifty million gallons. If two million gallons were applied to an acre in sixteen hours, or the equivalent of three million gallons in twenty-four hours, and this were crowded into one-half its area near the bottom of the sand, by the lateral pressure of the water coming towards the underdrains through the ten feet of coarser sand on each side, the resistance would be like that of four and a half million gallons traversing six feet in depth of sand, for which the head required would be fifty-four hundredths of a foot.

As the circumstances here allowed of a loss of head through the sand of one foot, the remaining head, from fifty-four hundredths to one foot, was the amount allowed for increased obstruction through the sand due to air and to lower temperature.

By a similar process of computation the coarser sand occupying the remaining twenty feet of the thirty feet between underdrains was found to be able to convey its proportion of the water to the underdrains with a like loss of head; hence the arrangement presented by these sections enabled all parts of the area of the filter to transmit nearly their proper quantity of water.

With this loss of head through the sand when clean, there would be a noticeable increase in loss by a slight deposit of sediment upon the surface, and depending upon this narrow margin it was deemed practicable to construct and use for a term of years a single bed which was to be cleaned regularly each month, a portion being

cleaned every day during the interval when the bed is resting; and this portion when cleaned is not capable of conveying so large a quantity of water that it cannot be properly purified in its passage, unless there be an extreme drawing down of the head which would require very close watching at the pumps.

When it becomes impracticable to properly purify the full amount of the city's supply by the present bed it is designed to construct another bed extending up the river from the intake, to be supplied by the second two-foot valve mentioned as built into the side of the chimney rising from the old intake.

We have followed the water through the sand and considered the head lost in its passage. There is still some head to be used in passing through the layers of stone and the underdraining pipes.

In considering the loss of head through fine sand and through coarser material to very large gravel stones, we find the loss increasing with the first power of the velocity, and with powers increasing with the coarseness from the first to the second power of the velocity; hence the most convenient method of presenting what our experiments have shown is in the form of a table which was used in distributing the remaining allowable loss of head of about half a foot in addition to the one foot through the sand, so that it should still serve to make the passage of water nearly uniform from all portions of the surface of the bed.

This table, though capable of improvement by additional data, led to conclusions which proved satisfactory in this case.

By the aid of this table the underdrains, formed of layers of stones of different sizes, were proportioned as shown in the accompanying plan and sections. The larger stones were selected by hand, and if soiled were washed. The smaller sizes were selected by screening, and in this way all sand was removed. The stones of the two larger sizes were carefully placed at the open joints of the pipes to allow water to enter as freely as possible; the other layers were shovelled to place.

In extension of the old filter-gallery, to serve to conduct the water from the down-river underdrains to the gallery, a conduit was built with walls four inches thick of brick laid in Portland cement mortar, with the mortar left out of the end joints, which were a little more than an eighth of an inch wide. This conduit was two feet in diameter for a length of 105 feet, then 20 inches in diameter for a length of 120 feet, then 16 inches in diameter for a length of 65 feet, then 12 inches in diameter for a length of 30 feet, beyond which were ten-inch, eight-inch and six-inch glazed pipes, in lengths of 30 feet, laid as in the underdrains. This conduit was surrounded by the large stones 2 inches in diameter for a thickness of 4 inches, with layers of decreasing sizes around this, making a total thickness of about 8 inches.

Great care was taken to deposit the filtering sand so that the mass should be as homogeneous as possible. It was deposited in two layers. The first layer was covered with planks as fast as laid, upon which the loads were hauled, and these were dumped upon the planks near the edge, so that a part of the load ran over the bank and the other part was shovelled over. If the edge of the bank remained exposed to the wind and sun the coarser material would appear on the surface and run down. Such an edge was shovelled over before an addition was made.

The second layer was dumped upon the planks resting upon the lower layer and shovelled up to grade, and upon taking up the planks the lower layer was shovelled over to the depth of one foot and a half to remove the packing of the sand which was evident under the planks, sometimes to a depth of one foot.

It will be evident that watchful care was necessary in laying the underdraining stones to see that no bar of finer material crossed it in any direction. In fact, the success of the filter depended largely upon careful and conscientious superintendence of the construction of the underdrains and the bed. This was accomplished by Mr.

Charles C. Campbell, who had an intelligent appreciation of the essentials to success and most scrupulous care that the work should be done as directed.

Sand for the filter was obtained from a bank about seven-eighths of a mile away, where layers and pockets were found containing all kinds, from the very fine, almost impervious, sands to large gravel stones, and much unsuitable material had to be removed in selecting layers from which suitable sand could be obtained. By judicious selection, screening and mixing the two kinds of sand were obtained and wheeled to piles for loading. These piles were frequently tested by half filling with sand a cylinder six inches high and three inches in diameter, having a wire bottom. The sand was packed slightly and covered with a wire screen and the cylinder filled with water, and the time observed that it took the water to pass below the surface of the sand. Time limits for the two grades were determined at the laboratory, making correction for the temperature of the water, and the accuracy of these tests at the bank was determined by occasionally taking duplicate samples to the laboratory and making regular mechanical analyses by means of sieves.

The filter was completed, at a cost of about \$65,000, in the forenoon of Sept. 20, 1893, just about one year from the time of commencing, although there were four or five months when work was suspended; and in the afternoon of September 20 the inlet gate was opened and the water filled the open conduit along the base of the embankment, ran into the carriers, and gradually flowed over the one and one-third miles of level edge and entered the sand, disappearing in a short distance at first, but gradually as the sand was filled extending further from the carriers and filling the bottom of the twenty-six valleys, and then rising slowly up their sides and covering the ridges, forming a shallow pond of two and a half acres. Then the pumps were started, and when running at the rate of five million gallons in twenty-four hours we found that the difference in level between the water over the filter and in the pump-well was seventeen inches.

The water first coming through the filter contained an extremely fine dust in suspension, probably washed from the surfaces of the stones and underdrains. In the first ten days the chemical changes in the water were as follows: the albuminoid ammonia was reduced from 0.0168 to 0.0108 in parts per 100,000. The free ammonia was reduced from 0.0113 to 0.0072, and the nitrates were increased from 0.0120 to 0.0200 part. The color was reduced from 0.36 to 0.28

the scale for color. Since that time the average change has been in albuminoid ammonia from 0.0187 to 0.0104; free ammonia from 0.0067 to 0.0087, and the nitrates from 0.0140 to 0.0390 part, and the color reduced from 0.42 to 0.35. The hardness of the water has increased from 1.3 to 2.9.\* This change is probably partly temporary, due to absorption of lime from the conduit and carriers, but it is partly due to ground water, as it was the greatest when, in the latter part of February and early part of March, there was the greatest loss of head through the filter and consequently the greatest draft from the ground. At the same time there was an increase in the free ammonia of the filtered water, evidently due to the same cause; but this cause was an exceptional condition due to the surface of the bed not having been cleaned for three months, which will probably not occur again.

While the improvement of the water by the removal of the suspended matter and the burning up of the organic matter that was readily oxidizable was very satisfactory, the most important change and the real object of the construction of the filter was the removal of bacteria, and especially of those kinds of bacteria that are dangerous to health, known as disease germs.

The removal of bacteria is not merely a straining process; it is accomplished by making conditions unfavorable to the life of bacteria in the passage through the filter, which conditions grow with the proper use of the filter. In the first three days 75 per cent. of the number of bacteria applied came through the filter. In the next three days 30 per cent. came through, but in the first week in October only 4 per cent. came through, and in the next week 2 per cent.; that is, during the first three weeks' use the number of bacteria in the effluent rapidly decreased to 2 per cent. of the number applied, and from that time to the present,† excepting on two occasions when work on the filter or in the pump-well interfered with the results, the effluent from the filter has contained 1.7 per cent. of the number of bacteria contained in the river water, the filter having removed 98.3 per cent. of all of the bacteria in the water applied to it.\*

But the result given to the people is better than this. It appears that with the removal of those parts of the organic matter that are

---

\* For results in detail of examinations of water from the Lawrence water works before and after filtration see pages 530-541, also 181-186.

† June 1, 1894.

easily oxidized the food material of the bacteria has been removed, and as the water flows on through the reservoir and through the pipes the conditions of life are still unfavorable for the bacteria, and they go on decreasing, so that the numbers found at the outlet of the reservoir are but one and two-tenths per cent. of the numbers in the river water; and at the tap in the city hall the numbers of bacteria found are but nine-tenths of one per cent. of the numbers in the river water. More than ninety-nine per cent. of all of the bacteria of the river water have been removed.

The experiments of the State Board of Health go to show that with this result we can rely upon the complete extinction of all of the disease producing germs that may have been in the water.

We have seen the effect of the filter upon the bacteria of the water applied to it; we will now seek the effect of the filter upon the inhabitants of Lawrence. It has been stated that the deaths from typhoid fever in Lawrence were about three times those of other cities in the State. Its relation to other cities from a broader field is shown by the following diagram, in which are given the percentage of mortality from typhoid fever to the total mortality in London, New York, Boston, Philadelphia, Chicago and Lawrence.

*Diagram showing Percentage of Typhoid Fever Mortality to Total Mortality in London, New York, Boston, Philadelphia, Chicago and Lawrence from 1870 to 1893.*

That the typhoid fever that has in the past affected Lawrence so seriously has come down the river year after year may be confirmed by the following diagram containing three broken lines. The heaviest

*Diagram showing Deaths per 100,000 Inhabitants in Boston, Lowell and Lawrence from June, 1889, to May, 1894.*

line indicates the number of deaths from typhoid fever in 100,000 inhabitants in the city of Boston in each month in the past five years. This line represents approximately the number of deaths from this disease in 100,000 inhabitants in the cities of the State and the months in which they occur. It will be seen that the months of greatest prevalence are September and October of each year. A vertical line has been drawn at such time of prevalence in each year at Boston, and this is nearly the time of its prevalence in our cities generally.

We see that in these months the disease prevailed to as great an extent in Lowell and Lawrence, but that following this period in about two months it prevails at Lowell to a much greater extent, and one or two months later it prevails to a still greater extent in Lawrence. This is the case year after year until during the past winter, when in February and March there was an increase in Lawrence following that at Lowell, but instead of being in greater numbers, as in former years, it was to only about half as many per 100,000, and the cause of this increase will now be considered.

In the following diagram the average number of deaths from typhoid fever at Lawrence for each month from October to May, in the preceding five years, are given by the heavy dotted line; and

the number during the past eight months are given by the heavy full line.

*Typhoid Fever in Lawrence.*

The total number for the eight months in past years has been forty-three, and in the present year seventeen, making a saving of twenty-six. Of the seventeen who died nine were operatives in the mills, each of whom was known to have drunk unfiltered canal water, which is used in the factories at the sinks for washing.

The finer full line shows the number of those who died month after month who are not known to have used the poisoned canal water. The whole number in the eight months is eight.

It is evident from the previous diagram that the numbers above the fine full line, here, follow after those at Lowell in the usual time, and were undoubtedly caused by the sickness at Lowell; but we have satisfactory reason to conclude that the disease was not propagated through the filter but that the germs were conveyed directly into the canals and to those who drank of the unfiltered canal water. Among the operatives of one of the large corporations not using the

canal water there was not a case of typhoid fever during this period. Warnings have been placed in the mills where canal water is used to prevent the operatives from drinking it.

We find, then, that the mortality from typhoid fever has, during the use of the filter, been reduced to 40 per cent. of the former mortality, and that the cases forming nearly one-half of this 40 per cent. were undoubtedly due to the continued use of unfiltered river water drawn from the canals.

The effect of the filter in preventing the communication of diarrhœal and other diseases carried by water can be given after the season of the year when these diseases prevail. We can say further at present that the physicians have very generally reported a marked improvement in the health of the people since the filter came into use.

The study of this problem and its solution have established with more of certainty than ever before three important points in sanitary science : —

1. The insufficiency of the self-purification of streams.
2. The ready conveyance of typhoid fever down a stream by sewage-polluted drinking water.
3. The practicability of protecting a community against an infected drinking water supply by natural sand filtration.

SEWAGE PURIFICATION  
OF  
CITIES AND TOWNS IN MASSACHUSETTS.

---

## SEWAGE PURIFICATION OF CITIES AND TOWNS IN MASSACHUSETTS.

---

The last annual report (1892) contained a paper upon the "Sewage Disposal of Cities and Towns in Massachusetts by Intermittent Filtration," which was accompanied by chemical analyses of the sewage and effluent from the works of the three places described, viz. : Framingham, Marlborough and Gardner. Owing to the time required for the publication of that report it was feasible to include in it analyses made up to the end of July, 1893. In the present paper results from sewage disposal works at several additional places are given, and analyses of sewage and effluent from the three places mentioned above are included only from the first of August to the end of the year. A short description of each of the systems examined is given in the following pages, and to assist the reader in understanding the conditions at the various places some of the statements made last year are repeated.

The first plant for the disposal of town sewage by intermittent filtration in Massachusetts was constructed at Lenox in 1876. A system for the disposal of the sewage of a portion of the town of Amherst, partly by filtration but chiefly by irrigation, was constructed about 1881, and a small system for the disposal of sewage by intermittent filtration was introduced at Medfield in 1886. Since the last date the towns of Framingham and Gardner and the city of Marlborough have constructed and are now operating works for the disposal of sewage by intermittent filtration, and a new disposal field has been constructed and is in use at Lenox. The city of Brockton (population in 1890, 27,294,) is at present constructing works of this kind, which will be operated in 1894. There are, also, several large institutions which dispose of their sewage by intermittent filtration. The sewage of the city of Worcester is treated by chemical precipitation, as described on page 341 of this report.

In order to learn the results obtained by the systems of sewage disposal in the various places, the State Board of Health has caused many analyses of the sewage and effluent from the filter-beds at Framingham, Gardner and Marlborough to be made, and has also made one or more chemical examinations of the sewage and effluent from the sewage disposal works at Amherst, Lenox, Medfield, Westborough and Wellesley College. The results of these analyses are given in connection with a description of the works in the pages which follow. Analyses made by the chemists at Worcester, showing the results obtained at the chemical precipitation works there, have already been given on page 345.

#### SEWAGE DISPOSAL AT AMHERST.

The population of the town in 1890 was 4,512. Sewerage facilities have been provided only for portions of the main village, and the sewage is disposed of by two systems.

The first system, begun in 1881 and subsequently extended, collects the sewage from about 1,000 inhabitants. The sewage flows to a settling tank about a mile south-east of the village and thence through a pipe 520 feet long into Fort River.

By the second system, since 1886, the sewage of a portion of the thickly populated part of the town north of the town hall has been applied, after settling in a tank, to a field having an area of about three acres and a slight slope, located about half a mile north of the village. It is said that there are about 300 people connected with this system, and storm-water is excluded from the sewers. The sewage is conducted by a ten-inch pipe to a settling tank located on the upper side of the disposal field. The tank is about 4 feet deep and holds about 500 gallons. The outlet pipe is arranged to avoid drawing the scum from the surface of the tank, and discharges into a long ditch running along the upper side of the field, from which the sewage is discharged through openings in its sides. The place of discharge is changed from time to time by blocking up the existing opening and making a new one. The sludge from the settling tank is removed at intervals and composted. Analyses of the sewage before and after settling in the tank are given below. There is no opportunity to obtain a sample of the effluent from this field, as the sewage sinks into the ground and does not reappear in such a way that a sample can be collected.

Iron, in each sample, .0080. Odor, distinctly vegetable, disappearing on heating. — The first sample was collected about 500 feet above the sewage disposal area and the last a very short distance below it. Sewage had been discharged upon the area about 6 hours before the samples were collected.

It is evident from the analyses that no sewage effluent was present in the sample collected below the disposal area.

## SEWAGE DISPOSAL AT FRAMINGHAM.

The town of Framingham (population in 1890, 9,239,) contains three villages, of which South Framingham is by far the most populous, and up to the present time is the only village sewered.

The sewerage system was put in operation near the end of the year 1889, and at the end of the year 1893, 610 dwelling-houses and 41 business blocks, stores, factories, etc., were connected with the sewers. In addition to this the sewage of the women's prison (population about 350), located in the town of Sherborn, just beyond the Framingham line, is taken care of by this system.

Storm-water is excluded from the sewers, and a continuous system of underdrains was laid beneath the principal sewers to collect and carry off the ground water. The amount of sewage flowing during a season of high rainfall, however, is fully three times the ordinary flow. The main underdrain discharges by gravity into a brook, and the character of the water discharged by it can be seen by reference

to a table of analyses on page 153 of this volume.\* The average amount of sewage pumped and purified in 1893 was 218,000 gallons per day.

The sewage, after collection in a pair of receiving reservoirs having a total capacity of 431,000 gallons, is pumped during the day-time to the filtration area, which is located about two and one-half miles north-east of the village of South Framingham. This area, a more detailed description of which, accompanied by a plan, may be found in the annual report of the Board for 1892, page 560, covers about seventy acres, much of which is quite level and at an elevation of about 20 feet above Bannister Brook. An area of about twelve acres has been specially prepared for filtration by dividing it into ten beds of convenient size, removing most of the loam, which was used in the construction of embankments between the beds, and by levelling the surface. Six of the beds are underdrained to a limited extent.

In 1893 about nine acres of the prepared beds were planted with field corn (maize), and the remainder with squashes, beans, potatoes and cabbages. The crops were very satisfactory, especially the field corn, and received only ordinary attention. The preparation of additional filter-beds is under way in order to increase the area to be devoted to farming purposes. The present area, however, is amply sufficient for the disposal of the sewage.

A reasonable objection has often been made to the cultivation of crops in connection with intermittent filtration, where the area is small, owing to the danger that, in order to avoid injuring the crops, the flow of sewage at certain seasons of the year will either be concentrated on a small portion of the area or allowed to escape unpurified. In the case of Framingham, however, the cultivation of crops has had a favorable effect upon the purification of the sewage by inducing the preparation of additional filter-beds, by loosening the soil by ploughing and other disturbances of the surface incident to cultivation, and by the removal by the crops of matters brought to the beds in the sewage.

The surfaces of nine of the filter-beds were left during the winter of 1893-94 in hills and furrows, and without disturbance, after the crops

---

\* Analyses of water from this underdrain are also given in the annual reports of the Board for 1890, 1891 and 1892, pages 149, 131 and 126, respectively. The first sample analyzed was collected before any sewage had been admitted to the sewers, and the character of the water has not changed materially since sewage was admitted.

had been removed from them. The remaining bed was ploughed and wide furrows made, about 6 feet apart, at right angles to the carriers along the side of the bed from which the sewage is applied. It was found that this bed gave the most satisfactory results, particularly when there was much snow on the ground. It is also to be noted that the beds where the surface is left in hills and furrows are much more efficient in winter than beds with level surfaces.

The quality of the sewage and of the effluent from several different places may be seen by the tables of analyses on the following pages. The sewage is ordinary town sewage, discolored and somewhat modified in character at times by a considerable amount of spent dyes discharged into the sewers from the straw goods factories in the town.

With regard to the purification effected at Framingham it may be said that the conditions for filtration are very favorable, owing to the large area of land in use in proportion to the amount of sewage treated, the porosity of the material, which has an effective size of 0.32 to 0.42 millimeter, and the depth to ground water. Another favorable condition is the high temperature of the sewage in winter (48° to 50° F.) due chiefly to the fact that the water supply of the

\* This average is for the whole year 1893, and includes the results of analyses made during the earlier part of the year and printed in the preceding annual report.

town is taken from the ground and has a winter temperature of about 49°.

Only a small portion of the effluent is collected by the underdrains beneath the beds, and of this quantity all or nearly all again enters the ground and receives a second filtration before it reaches the brook, while most of the effluent passes for a long distance through the ground and appears in the form of springs at the edge of the low land near the brook. The existence of lateral filtration to such a marked degree is believed to be a very important feature of the Framingham filter-beds.

The average degree of purification of the applied sewage in 1893, as indicated by the albuminoid ammonia in the analyses, is as follows:—

|                                        | Per Cent. of<br>Organic Matter<br>Removed<br>(Albuminoid<br>Ammonia). |

### SEWAGE DISPOSAL AT GARDNER.

The Gardner sewerage system was put in operation about Aug. 1, 1891. At the end of 1893 there were 161 connections with the sewers, 120 of which were from dwelling-houses and the remainder from factories, business blocks, hotels and public buildings. The population of the town in 1890 was 8,424. With the exception of roof-water, used for flushing purposes, from a limited number of buildings at the upper ends of the sewers, surface water is excluded. The quantity of sewage is not definitely known, but it is probably not far from 200,000 gallons per day in dry weather.

The tract purchased by the town for the disposal of the sewage contains 16.9 acres. Much of the material upon this tract was found to be too fine for the filtration of sewage, and, as a result, the filter-beds are almost wholly artificial, being formed of the porous sand and gravel from a ridge upon this tract. There are twelve thoroughly underdrained filter-beds for the disposal of sewage, having a total area of 1.39 acres, two supplementary beds which are less porous and not underdrained, having a total area of 0.37 acre, and two other small underdrained beds, containing together 0.14 acre. One of these

small beds is used to receive the sludge from the sludge tank, and the other to receive the discharge from a blow-off located at the lowest point in the pipe leading from the town, which, for the last 1,050 feet of its length where it crosses the valley of Pond Brook, is an inverted siphon. This bed was not used in 1893, however, because it has been found that if clogging occurs the sewage backs up in the pipe until sufficient head is obtained to remove the obstruction. The material of the filter-beds has an effective size of 0.10 to 0.24 millimeter, which is somewhat coarser than at Marlborough but much finer than at Framingham. The underdrains beneath the beds are generally twenty feet apart and at a depth of from four to five feet below the surface of the beds.

The sewage, when it reaches the disposal area, first passes through duplicate separating tanks having a total capacity of about 10,000 gallons, and overflows through wooden troughs upon the disposal area, as described in the annual report of the Board for 1892, page 580.

It has been the custom, except during the winter months, to apply sewage to one-half of the beds one day and the other half the next, and once in ten days or two weeks to remove one-eighth to one-quarter inch of scum and clogged sand, and afterward to rake to a depth of about 1.5 inches to loosen the material. Below this depth the material is compact to a depth of several inches.

\* This average is for the whole year 1893, and includes the results of analyses made during the earlier part of the year and printed in the preceding annual report.

The results obtained at Gardner have been satisfactory in the summer, but, as stated in the last annual report, in order to obtain these results it has been necessary to attend carefully to the distribution of the sewage upon the different beds, and to remove at frequent intervals the scum which forms upon them. During cold weather when the removal of this scum is prevented by snow and ice upon the beds, it has not been found practicable to filter the sewage upon the small area provided, and a portion of it has overflowed into the brook. In December, 1893, the surfaces of the filter-beds remained smooth, and were unprepared by ridging or otherwise for use in cold weather, and during the latter part of the month the sewage froze to the surfaces of some of the beds. The remaining beds were used beyond their capacity and remained constantly covered with sewage, thereby making the filtration continuous, while a considerable quantity of sewage overflowed into the brook. The effluent of the portion of the sewage filtered through the beds deteriorated in quality when cold weather began.

The analyses of sewage and effluent from the Gardner filter-beds, from August to December, 1893, are given in the following table. The averages of analyses for the whole year 1893 show that, of the sewage filtered, 91.1 per cent. of the organic matter (as represented by the albuminoid ammonia) was removed from the sewage by filtration.

Iron, .0222. Odor generally distinctly musty, occasionally offensive. — The samples were collected from the brook below the filter-beds, and below the points where effluent from the filter-beds enters the stream.

## SEWAGE DISPOSAL AT LENOX.

The village of Lenox is situated upon high land, from which the ground slopes to the west, south and east. The first attempt at sewage purification was made in 1876 at a small field upon the westerly slope of the hill. In 1881 the sewage of a few houses on the southerly slope of the hill was conveyed to a small tract of land at the foot of the hill in the town of Stockbridge and there disposed of. In 1888 the principal sewerage system of the town was completed, and by it the sewage is conveyed to a disposal field about two miles east of the village and near the Housatonic River.

This system diverted much of the sewage which formerly went to the small field on the westerly slope of the hill, but, notwithstanding the reduced quantity of sewage going to this field and the small quantity going to the southerly field, the neighboring land owners objected to the use of these areas for sewage disposal, and in December, 1893, works were completed for collecting the sewage of the westerly and southerly slopes at a pumping station west of the village and for pumping it into the main system of sewers leading to the easterly field, which will be the only one in use after the pumping station is operated.

The sewers of Lenox are pipe sewers, and storm-water is excluded from them, except a small quantity of roof-water, which is admitted for flushing purposes. There are said to be about 1,000 persons connected with the system ordinarily, but during the summer season the number is more than doubled.

The main pipe leading from the village to the easterly disposal field is twelve inches in diameter, and ends at a settling tank on the upper portion of the hillside, about 800 feet from the Housatonic River. The tank is of masonry, and has two separate compartments. There are two overflow pipes, one discharging into a pipe connecting with the sub-surface disposal system and the other with a pipe which has a direct connection with the river. There is also a pipe at the bottom of the tank through which the sludge can be run out whenever the tank needs cleaning.

The sewage is disposed of beneath the surface by turning it into stone drains, which are long, nearly-level trenches, filled with stone up to within a short distance of the surface, and above the stone with earth and loam. In addition to the stone the trench contains a six-inch Akron pipe, with open joints, through which the sewage

from the settling tank is conveyed to the drains. These drains vary in length from 200 to 800 feet.

Beneath these stone drains are underdrains, about thirty feet apart, running down hill toward the river. The underdrains are laid with tight joints where they pass beneath the stone drains and with open joints between the drains.

The material of the disposal field is compact and nearly impervious, so that only a portion of the sewage will filter through the ground and the remainder flows out from the stone drains upon the surface through relief pipes which have been laid at their farther ends, or passes off into the river through one of the overflow pipes at the settling tank.

In the following table will be found analyses of sewage and effluent taken from different points of the Lenox system. The sewage is very dilute, owing to the large amount of ground water entering the sewers. It may be noticed, by reference to the table, that the second and third samples, taken from the settling tank after some precipitation had taken place and from the ends of the stone drains, are much less impure than the first sample, which was collected from the main sewer. There was, doubtless, some improvement in quality caused by the passage of the sewage through the settling tank and through the drains, but the bulk of the difference is probably due to the fact that the sewage from the main sewer represented the day sewage, while the samples from the tank and drains represented to a greater extent the night flow, the larger proportion of which is ground water.

The first sample was collected from the sewer which conveys sewage from the town; the second, from the main settling tank; the third, from the ends of the sub-surface pipes in the stone drains; the last, from the outlet of the underdrains.

### SEWAGE DISPOSAL AT MARLBOROUGH.

The sewerage system of the city of Marlborough (population in 1890, 13,805) was completed late in 1891, and at the end of 1893 there were about 800 connections, including those from all of the larger places, such as hotels, factories, etc. The total length of sewers was 21.58 miles. The so-called separate system was adopted, but no underdrains were laid beneath the sewers and a large amount of ground water enters them at certain seasons of the year.

As the sewage arrives at the disposal field it passes through separating tanks and screens before passing into the distributing pipes. The tanks are built in duplicate, to facilitate cleaning, and, including the portions where the screens are situated, are each about twenty-five feet long, six and one-half feet wide and six feet deep. The screens are of wire and have a one-inch mesh. The elevation of the tanks above the sandy land is such that it was feasible to prepare beds upon which the sludge deposited in the tanks could be turned by gravity.

Thirteen sewage beds, with a total area of 9.6 acres, and six sludge beds, with a total area of 1.7 acres, have been prepared for the disposal of the sewage and the sludge. The material of the beds is finer than that of Framingham and Gardner, and has an

effective size of 0.12 to 0.14 millimeter. The area has a moderate slope toward a small brook, and is from seven to twenty-two feet above it. The beds are thoroughly underdrained by means of parallel lines of four-inch pipes, laid with open joints fifty feet apart and about six feet beneath the surface. All of these drains discharge into the brook before mentioned.

The sewage is ordinary city sewage, varying in strength from time to time with the amount of ground water which enters the sewers. The average quantity is not definitely known, but it was probably in the neighborhood of 400,000 gallons per day during 1893.

Previous to December, 1893, it is said that the beds were generally flooded in turn for twenty-four hours, but that, beginning with this month, they were flooded in turn as before, but for only half a day at a time, and the results obtained from this treatment show, apparently, an improvement. The beds were harrowed twice during the year, about the first of May and the first of November, with a wheel-harrow, to a depth of four to six inches. In November no leveller was attached to the harrow, and the surface was left in alternate ridges and furrows. The grass and weeds were cut several times during the summer, and in the fall several beds, where the weeds grew more luxuriantly, were ploughed before harrowing. A considerable portion of the sludge in the sewage passes through the separating tanks and in time forms a thick scum upon the surfaces of the filter-beds. This scum was removed at irregular intervals during the warmer months, but not during the winter. As a general rule the scum was removed before the surfaces were ploughed or harrowed.

With the aid of the furrowed surfaces and the application of smaller doses the filters disposed of the sewage during the winter months with satisfactory results. At times there has been considerable odor from the sludge beds, but as the beds are a long distance from any road or habitation this has not been a source of complaint.

It has not been the custom to employ a man constantly in caring for the beds, but to employ a man living in the neighborhood to attend to changing the flow of sewage from bed to bed, and to remove the scum from the surfaces of the beds, paying him by the hour for the time spent on the work. The cost of all work done on the beds during the year 1893 amounted to \$497.19.

The averages of the analyses for the whole year 1893 indicate that 94.2 per cent. of the organic matter, as represented by the albuminoid ammonia, was removed from the sewage applied.

Iron, .0094. The first sample was collected from the brook above the filter-beds; the remaining samples from the brook below the filter-beds after it had received the effluent therefrom.

## SEWAGE DISPOSAL AT MEDFIELD.

A system of sewage disposal by intermittent filtration was introduced at Medfield in 1886, and was described in the Nineteenth Annual Report of the Board for the year 1887. Up to the end of 1893 connections had been made with one hotel, three houses and a large straw factory, in which, at times, as many as 900 operatives are employed. The original area of the beds was about one acre. The material is mostly coarse gravel. As the level of the ground water is about ten feet below the surface of the filter there are no underdrains. There are four beds, the surfaces of which are some-

The samples were collected from the spring which is located north of the filter-beds and a little over direction of this spring.

what uneven, each of which, as a general rule, takes the sewage in turn for two days. It was found that there was considerable loam a short distance below the surface of a portion of the beds which eventually became clogged. In the summer of 1893 this loam was removed and replaced with coarse gravel, and the area of the filter increased about one-third.

No trouble has arisen from odors. In the following tables will be found analyses of the sewage, and of the effluent taken from a spring a short distance below the filter. The effluent is of excellent quality, and no deterioration is shown by the analyses when compared with those made in 1887, after the works had been in operation for a comparatively short time.

After this clogging occurred provision was made for screening the sewage so as to prevent the entrance of coarse substances into the eight-inch pipes.

In the summer of 1893 some further changes were made. Two settling tanks, each ten feet long and six feet wide, were added, and the length of the filtration area was extended to 450 feet, making the total area 1.55 acres. All of the sub-surface distributing pipes were relaid, and over the joints of the pipes, in all cases, were placed pieces of half-pipe of larger diameter. An eight-inch pipe was laid along each side of the filtration area and connected with the ends of all of the three-inch distributing pipes. Gates have been placed at the lower ends of all of the eight-inch pipes, and about once a week, usually on washing day, they have been opened with a view to flushing the entire system of pipes. The sewage used in flushing discharges upon a thin filter-bed about fifty feet square. It has been the custom to empty the settling tanks once a week, and at these times the liquid matter is discharged upon a small filter-bed constructed for this purpose, while the semi-solid portions remaining are run into carts and removed to some woods at a considerable distance from the buildings where they are disposed of by composting. There are about 500 people connected with this system. There have been no indications of clogging in the sub-surface pipes since the changes were made.

In the following tables will be found analyses of the Wellesley sewage, and of samples of water taken from a small brook, into which some of the effluent finds its way, above and below the filter-bed.

Iron, .0878. Odor of the first sample, none; of the second, faintly earthy; of the last, strong of gas liquors. On heating, the odor of the first two samples was distinctly vegetable, but the last was unchanged.—The first sample was collected from the brook above the filter-beds; the second, near the sludge bed, and the last, near the gas works, about 150 feet above the point where the brook enters Waban Lake.

### SEWAGE DISPOSAL AT WESTBOROUGH.

The construction of the sewerage system of the town of Westborough (population in 1890, 5,195) was begun in 1891, and up to the end of the year 1893 ninety-one connections had been made with the sewers, forty-three of which were from the larger places, such as business blocks, factories, etc. The main sewer leading from the town to the place of disposal passes through low wet ground, and receives a large amount of ground water.

The sewage is disposed of upon land located on the right bank of the Assabet River, in the north-westerly part of the town. About thirty-three acres were taken by the town for sewage-disposal purposes, 17.5 of which may be classed as swamp or meadow subject to flooding at times of high water, its surface being at an elevation of three feet or less above the ordinary level of the river. About six acres of the upland is at too great an elevation to be reached by gravity without grading.

The sewage is conducted to a settling tank on the disposal area. The tank is of masonry, built in two compartments, and has a total capacity of less than 1,000 gallons. Two filter beds, having a total area of a little over two acres, were prepared in 1892 by stripping off most of the loam and filling with coarse sand or gravel to depths varying from about thirty inches at the lower end to about a foot at

the other end. The material beneath the filling is a fine, compact sand almost impervious to water. The surfaces of the beds are from six to six and one-half feet above the ordinary level of the surface of the water in the Assabet River, opposite the sewage field. During the prevalence of high water in the spring the surface of the water in the river rises to about three feet above the ordinary level.

Sewage was applied to the beds in April, 1893, and it was found that the sand beneath the artificial and porous surface layer was so fine that it remained saturated and also kept the material above it saturated for weeks after the application of sewage had ceased. It is said that these beds could be made to take the whole flow of sewage for about a week by filling them to the level of the top of the embankment. On discontinuing the use of the beds in July it took eight weeks for the sewage to disappear.

To obtain material to prepare the filter beds as above described, a pit was excavated in a gravel ridge in the higher portion of the area owned by the town. Into this gravel pit, covering an area of approximately 15,000 square feet, the bottom of which is said to be six inches above the ground-water level, the sewage has been discharged from time to time, and it has been filled to the level of the bottom of the sewage carrier, or approximately six feet deep, forming a huge cesspool, the effluent from which appeared in the form of a flowing spring, on the surface of a piece of low land fifty to seventy-five feet from the edge of the excavation. During the year 1893 sewage has also been discharged from time to time on a portion of the unprepared ground and allowed to flow over its surface to find its way to the meadows.

The selectmen of the town applied to the State Board of Health, Sept. 18, 1893, stating that the former advice of the Board had not been carried out, and requesting the Board to make another examination of the present sewage-disposal works at Westborough, and advise the town farther in the matter of sewage disposal. The reply of the Board to this application may be found on page 86 of this volume.

Toward the end of the year the surfaces of the two filter beds were raised from one to two feet by the addition of more coarse sand, and two six-inch underdrains were placed beneath the beds at depths of from three to five feet beneath the surface. In addition to this work, two additional beds, each about an acre in area, were prepared between the settling tank and the river. The surfaces

of the new beds were levelled to some extent, and in each two four-inch underdrains were laid three feet below the surface at the upper ends and five feet below at the lower ends. It is said that some of the mud in the low places on the area covered by these beds was removed while preparing the beds and replaced with gravel from a knoll situated partly within the limits of the beds. There is considerable loam remaining on each bed. Sewage was distributed

The first and last samples were collected from the spring below the gravel pit; the second

upon the two new beds from trenches along the sides and by furrows across the beds. The distribution, however, at the time the beds were examined was very uneven.

In the following table will be found analyses of samples of the sewage, of the effluent from the gravel pit collected at the spring already mentioned and of samples collected from the Assabet River above and below the disposal area.

# CHEMICAL PRECIPITATION OF SEWAGE AT THE WORLD'S COLUMBIAN EXPOSITION, CHICAGO, 1893.

---

BY ALLEN HAZEN,\*

CHEMIST, DEPARTMENT OF WATER SUPPLY, SEWERAGE AND FIRE PROTECTION.

---

The sewage disposal works at the World's Columbian Exposition were described in the "Engineering News" of Aug. 3, 1893, which contains drawings showing many of the details of construction and arrangement.

The works were designed and built under the direction of W. S. MacHarg, C.E., engineer for water supply, sewerage and fire protection, Mr. C. M. Wilkes being first assistant engineer, and the construction of the plant and the operation of the machinery being superintended by Mr. C. E. Chester. The writer was employed to superintend the precipitation of the sewage after the construction of the works was practically completed.

The works consisted in brief of four cylindrical iron settling tanks of the Rückner-Rothe type, 32 feet high and 32 feet in diameter, with conical bottoms, which, in a height of 22 feet, tapered from 32 feet to 6 feet (see diagram on following page†). The total height was thus 54 feet, and the capacity of each tank, as ordinarily used with sewage standing 18 inches below the top, was 237,000 gallons.

The sewage from the various buildings on the Exposition grounds was forced by Shone ejectors into the iron sewers which terminated in a receiving tank 16 feet in diameter and 10 feet deep, where the sewage was screened and afterward passed through the four pipes which conveyed it to the different settling tanks, receiving and be-

---

\* Mr. Hazen, at the time of his appointment at Chicago, was chemist in charge of the Experiment Station of the Massachusetts State Board of Health at Lawrence. He held the position at Chicago during a leave of absence granted by the Board.

† The plate from which this diagram is printed was kindly furnished by the Engineering News Publishing Company.

coming mixed with the necessary chemicals on the way. The mixed and precipitated sewage then passed down through central cylinders, 6 feet in diameter, to points near the bottoms of the tanks, where it was distributed by sheet-iron arms and the precipitate settled to the bottom, while the clarified liquid, ready for discharge into the lake, slowly rose to the top, where it was removed by a set of troughs drawing as nearly as possible equal quantities of effluent from equal

areas of surface to give a uniform and regular upward movement to the sewage in the tanks. The sludge which settled to the conical-shaped bottom was expected to slide to the point of the cone, where there was an outlet through which it could be drawn off from time to time for pressing without interrupting the continuous action of the tanks.

The filter-presses, which were exhibited by the Perrin Company, Chicago, were made by the G. H. Bushnell Company, Thompsonville, Conn., and produced at each operation fifty cakes of sludge 36 inches in diameter and about  $1\frac{1}{4}$  inches thick, weighing about 47 pounds each. The central passages in the filter-presses were 4 inches in diameter, but it was found that rags and cotton waste which passed

the bars in the screen, about three-fourths of an inch apart, would frequently stop the 4-inch holes in the plates, allowing the pressure to accumulate on one side of the plate until it broke. The delay and expense of replacing plates was considerable, and it was not until the screen was covered with a finer wire screen to retain all rags and the holes in the plates were cut out to six inches in diameter that satisfactory working was obtained. The quantity of sludge which could be pressed with these presses was much below the anticipated amount, and the failure to press promptly the sludge as produced was often the limit, during a large part of the summer, of the efficiency of the plant.

The sludge cake, together with the garbage from the grounds, was burned in an Engle crematory near the sewage-disposal works.

The object of having four separate settling tanks, each of them with its independent appliances for mixing chemicals, was to allow the simultaneous application of different chemicals to sewage of precisely the same composition, and to secure in that way definite comparisons between the different chemicals when working upon a large scale. Such experiments were made almost from the first, but it soon became apparent that, within wide limits at least, the chemicals employed were not the controlling or even the leading factor in the results obtained, and that the differences between the various quantities or kinds of chemicals were often far more than offset by other conditions, which will be described beyond, over which we had less control. In this way, our investigations, instead of throwing light upon the questions which we had propounded, have been mainly confined to quite another set of problems which were scarcely anticipated before they presented themselves. We found it necessary to study, not so much how to produce a precipitate by adding chemicals to the sewage, as how to make it settle to the bottom and stay there until it could be removed and pressed.

#### MANNER OF DELIVERY OF THE SEWAGE AT THE WORKS.

One of the most troublesome circumstances in connection with the plant was the irregular manner in which the sewage was delivered at the works. The flow of sewage, instead of coming regularly, was subject to violent fluctuations, due to the method of collection and to the construction of the force main. The sewage was forced into

this main by twenty-six pairs of Shone ejectors located at various points on the grounds. These were operated by compressed air from a central station in Machinery Hall, and each was furnished with an automatic appliance to shut off the air as soon as the tank was sufficiently emptied. For some reason these valves often failed to act as was intended and the compressed air followed the sewage into the pipes in large quantity, pushing ahead of it the sewage in the sewer pipes with great rapidity to the precipitation works. The sewer pipes having been laid without attention to grades, contained numerous summits and depressions, and the air rapidly accumulated in the summits until finally the bulk of the sewage in the sewers had been forced to the works when at last the air commenced to come through the vertical discharge pipe. This at once relieved the pressure and the large volume of air contained in the sewers, now rapidly expanding and mixed with varying proportions of sewage, came out with explosive violence, throwing quantities of sewage into the air and even through the roof. The violence of these "blows" can be somewhat appreciated when it is stated that most of the glass in the roof twenty feet above the outlet was broken by these "blows" within a few days after the works were started, and that among other debris, a piece of lead weighing nine pounds, which had been accidentally left in the sewers, was carried up through and discharged from the vertical pipe fifty feet in height.

The number of days in each month on which such "blows" occurred, usually from one to ten and sometimes even as many as twenty "blows" occurring in a single day, was as follows:—

|                   |          |                 |                              |    |   |   |   |
|-------------------|----------|-----------------|------------------------------|----|---|---|---|
| April (14 to 30), | 13 days, | or 76 per cent. | of the total number of days. |    |   |   |   |

| September,        | 22       | "               | "                            | 73 | " | " | " |
| October,          | 26       | "               | "                            | 84 | " | " | " |

The average maximum hourly flow of sewage was about 6 per cent. of the total daily flow, and the latter never exceeded 3,200,000 gallons; it may thus be said that the normal flow of sewage which should have been obtained, if it had been delivered at the same rate as it was produced, would not have exceeded 190,000 gallons per hour, and this quantity would produce a velocity of only a foot a second

in the three-foot discharge pipe. Actually, the ordinary discharge between "blows" was much less than this, and allowed much of the suspended matter of the sewage to be deposited on the bottom of the sewer. Every time a "blow" occurred the matter which had been deposited since the previous "blow" was flushed out, and at these times sewage was obtained two or three times as concentrated as at other times. Thus for short intervals enormous quantities of highly concentrated sewage were received at the works, and the rest of the time only a reduced flow of a sewage from which the sludge had been partially removed, and frequently for a time after the "blows" occurred there was no flow at all.

### PRECIPITANTS EMPLOYED.

The chemicals employed as precipitants were copperas or crude ferrous sulphate, crude alum or sulphate of alumina, a crude ferric sulphate, and lime. The copperas, alum or ferric sulphate was first added to the sewage, which then passed through a mechanical mixer containing a rapidly revolving paddle-wheel, and then received the lime. The mechanical mixers for mixing the chemicals with the sewage had no advantage over a fishway, and were more expensive and troublesome in construction and operation. The chemicals were added mainly in accordance with the principles given in the special report of the Massachusetts State Board of Health for 1890;\* but owing to variation in the market prices of the various chemicals and the freight the relative costs were changed somewhat.

The analyses and costs of the various chemicals employed, together with many other data, are given in the Appendices following (pages 613-624). In calculating the costs the actual costs of chemicals delivered in Chicago are given in each case, although much lower prices were paid for some of the later lots than at the beginning.

It was found that the sludge produced with copperas and lime as precipitants was much more easily pressed than that with alum, even when used with lime; and as the cost of pressing the sludge exceeded the cost of precipitating, copperas was a more economical precipitant than alum. For the same reason more lime was used with alum than was necessary to produce the best effluent, because

---

\* Experiments upon the Chemical Precipitation of Sewage, by Allen Hazen. Special Report of the Massachusetts State Board of Health upon Purification of Sewage and Water, 1890.

the sludge produced in presence of an excess of lime could be much more easily pressed, and the extra lime applied to the sewage was cheaper than the labor on the presses. For equal costs of treatment copperas and alum produced equally good effluents, although the effluent from copperas had more color (due to the suspended iron) than that from alum. The only ferric sulphate obtainable contained much free acid, with a disappointingly low percentage of soluble ferric oxide, and the rather poor results obtained should not be taken as disparaging the use of a better quality of reagent.

Two kinds of lime were employed, a very pure lime from Hannibal, Mo., and a local dolomite lime which was used at first, and on one or two occasions afterwards when the stock of Hannibal lime was exhausted. This lime cost only two-thirds as much and was hardly six-tenths as strong as the Hannibal lime, and to avoid unnecessarily complicating the figures in the tables given beyond, when dolomite lime was used, its weight is reckoned as its equivalent in cost of Hannibal lime, or two-thirds its actual weight.

#### MEASUREMENT AND COMPOSITION OF SEWAGE AND EFFLUENTS.

The quantities of sewage passing each tank were determined by hourly weir measurements, so that the total daily flow of sewage was calculated from ninety-six readings. Records were kept of all these quantities, and of the weights of the chemicals employed.

Many samples of sewage and of the different effluents were analyzed to determine the efficiency of the treatments, but to avoid an unnecessarily large volume of data, only the monthly averages are given below, as it is believed that no additional information of importance would be obtained from a more detailed presentation. The method of obtaining the samples was to mix eight pint samples in a gallon bottle, the eight portions being taken at such intervals that one-eighth of the total daily flow passed between each two of them. The samples of effluent were taken in the same way, but as much later than the corresponding sewage samples as the average time required for the sewage to pass through the tanks.

The analyses are believed to represent correctly the character of effluent as discharged into Lake Michigan; but, owing to the violent fluctuations in the flow of the sewage mentioned above, the samples of sewage taken represent in general the sewage between "blows,"

when it did not contain the full amount of sludge, as, owing to the personal danger involved, satisfactory samples could not be obtained during "blows," and even if they could have been collected, it would have been impossible to determine how much sewage actually had the composition indicated by the samples. For this reason the results for loss on ignition, albuminoid ammonia and oxygen consumed in the unfiltered sewage are too low and the results of efficiency given must be taken as relative instead of absolute. The soluble constituents, including chlorine and free ammonia, were not affected in the least by sedimentation.

The averages of analyses of sewage and effluents by four weeks' periods are as follows : —

## Period I. June 10 to July 7, 1893.

\* Determined after filtration through filter-paper.

One of the most striking features of these analyses is the excessive number of bacteria found in the effluents,—several times as many as in the crude sewage. The causes of this remarkable condition were investigated by Drs. Wilson and Agar of the United States Army Hospital. The results obtained show that, while the sewage contained a great variety of species of bacteria, the effluents contained only a few species in large numbers, and these forms were very much more abundant than in the crude sewage. It appears that the bulk of the bacteria of the sewage was taken to the bottoms of the tanks in the precipitate, and did not exist in the effluents. The tanks, however, served as a breeding place for enormous numbers of the species found in the effluents, which were, presumably, non-pathogenic, for, so far as we know, the pathogenic forms sometimes found in water are probably incapable of growing in the conditions present in the tanks. The treatment may be said to have secured a partial but probably very incomplete removal of objectionable bacteria.

#### THE WORK OF THE INDIVIDUAL TANKS.

The quantities of sewage treated and chemicals employed for each tank during the different periods and the costs of the chemicals are shown in the following tables :—

##### *Period I. June 10 to July 7, 1893.*

\* When dolomite lime was employed only two-thirds of its weight is used in this table.

† The percentage purification indicated by these figures is too low, owing to the partial sedimentation of the sewage analyzed, already referred to on pages 602, 603. The efficiency of the plant as a whole is discussed beyond. The figures for each period, however, are comparable among themselves.

## CHARACTER OF THE SLUDGE.

The quantity of sludge pressed was estimated by weighing an occasional representative pressing. No separate record could be kept of the weights of sludge from the different tanks. Analyses of the pressed sludge were made from time to time. Its composition was quite constant, the average result being —

\* When dolomite lime was employed only two-thirds of its weight is used in this table.

† The percentage purification indicated by these figures is too low, owing to the partial sedimentation of the sewage analyzed, already referred to on pages 602, 603. The efficiency of the plant as a whole is discussed beyond. The figures for each period, however, are comparable among themselves.

During May and June occasional "soft" pressings were obtained, which decreased the percentage of dry matter in the total output. The presses were but rarely able to press the sludge promptly as produced, and on two occasions, July 13 and September 4 to 6, it was necessary to discharge unpressed sludge into the lake to avoid a nuisance at the works. There was also a slight accidental discharge in October. The sludge was usually pressed without the addition of lime. With copperas as a precipitant the addition of lime to the sludge had little effect upon the rapidity of pressing. With alum as a precipitant the addition of lime allowed somewhat more rapid work, but the same result was obtained by mixing the sludge from copperas with the alum sludge.

The quantities of sludge pressed in the different periods are shown in the following table. The table also includes estimates of the quantity of sludge on hand and of the quantity discharged into the lake reduced to the basis of pressed sludge cake. These estimates, based in part upon the observed heights of sludge in the tanks at different times, are necessarily only rough approximations.

*Summary of Sludge Statistics.*

**EFFICIENCY OF THE PROCESS.**

As stated above, it was found that large quantities of insoluble matters were removed from the sewage by sedimentation in the sewers between "blows," and when "blows" occurred these matters were washed out, so that the sewage at these times was often several times as concentrated as at other times. The concentrated sewage is not properly represented in the sewage samples taken for examina-

tion owing to the difficulty or impossibility of getting samples at these times; or, in case samples were taken, of determining what proportion of the daily flow was of the same character as the samples. For this reason the efficiency of the plant, as calculated from the chemical analyses, is considerably below the actual efficiency. We have, however, a fairly satisfactory record of the quantities of organic matters in the sludge and in the effluents, and by adding them together we can obtain an approximate estimate of the matters in the sewage, which is probably much more accurate under the circumstances than the direct calculation from the average analyses.

| Total, June 10 to Oct. 27, | 2,330                                                                              | 410.7                                                                         | 235.3                                         | 230.2                                       | 465.5                                            | 49                                                                   |

This calculation indicates that for the entire period the error in the average analyses of the sewage was 12 per cent., but that during the first part of the time, when "blows" were less frequent the error was less and for the last two months, with almost continual "blows," the error was greater.

The calculation shows that as a result of the operation of the works for the twenty weeks for which complete data are available, substantially one-half of the total organic matters of the sewage was removed by the precipitation. This efficiency is slightly less than was indicated for the Worcester plant by the examination of the Massachusetts State Board of Health in 1891,\* and is less than we

\* Annual Report, 1891, page 267. [During this examination, which was made for the week ending July 29, 1891, the average amount of organic matter removed from the Worcester sewage was 56 per cent. Since Mr. Hazen's paper was written, the annual report of the superintendent of sewers of the city of Worcester for 1893 has been issued, and extracts from it may be found on pages 343-345 of this volume. As there stated, the average amount of organic matter removed from the sewage from July 19 to Dec. 1, 1893, was about 50 per cent. ED.]

had hoped to obtain. The experiments made at Lawrence in 1889\* had indicated that chemical precipitation might remove as much as 60 per cent. of the total organic matter of the sewage.

The above calculation includes practically the whole operation of the plant, with all the conditions as they actually existed. Some of the unfavorable conditions which have been mentioned could hardly have been anticipated, and in a permanent plant would have been rectified; but there was no opportunity for changes in the short time that the plant was operated in Chicago. With the single exception of the test of the Worcester plant for one week, mentioned above, I do not know of any results which can be fairly compared with these, as it is manifestly unfair to compare the entire operation of one plant with a single set of analyses from another plant, taken, perhaps, under the most favorable conditions possible; and it must be admitted that our knowledge in regard to the total result of the operation of other chemical precipitation works is extremely limited.

The erroneous impression which may result from a single set of analyses was well illustrated by the analyses of sewage and of effluents from the Chicago works taken at noon, August 14, when the sewage had reached its full strength, but while the effluent was mainly from the diluted sewage of the preceding night. The results of these analyses indicated that 88 per cent. of the organic matters of the sewage had been removed, and were of course entirely misleading.

The disappointingly low efficiency of the plant is, I believe, to be attributed solely to the unfavorable conditions for sedimentation present in the tanks. The violent fluctuations in the flow, indeed, made it impossible to apply the chemicals to the sewage with that regularity which is necessary for the best results, and the agitation of the sewage in passing from the outlet of the sewer to the settling tanks was such that minute air-bubbles were constantly inclosed in the precipitate, often causing it to rise at first instead of sinking; but in spite of these minor difficulties I believe comparatively good results would have been obtained had better opportunities for sedimentation been present. This is strongly suggested by the record of Tank 4, which, during the first three periods, was protected from the excessive flows at the times of "blows" by sending the extra volume through

---

\* Special Report of the Massachusetts State Board of Health on Purification of Sewage and Water, 1890.

the other tanks, and it so received a somewhat smaller and very much steadier flow. While the tank was so operated it constantly gave a very much better effluent than the other tanks, and for the whole period averaged a removal of 58 per cent. of the organic matters of the sewage passing through it at an average daily flow of 456,000 gallons, while all the other tanks for the same time removed only about 50 per cent. of the organic matters, with average flows of 635,000 gallons daily.

The prejudicial effect of these excessive flows for short periods is believed to be mainly due to the general stirring up which they gave to the contents of the tanks. They did not last long enough for any of the sewage coming in them to pass through the tanks before the ordinary rate was restored. The sloping surfaces of the bottoms of the tanks were always covered with more or less sludge, which was apparently to some extent loosened and mixed again with the sewage at these times, and did not again completely settle back, but was instead carried out by the effluent, reducing seriously the total efficiency.

It was shown by several series of chlorine determinations that the incoming sewage did not with any regularity displace the sewage previously in the tanks, but to a very large extent mixed with it, and a fraction of it appeared in the effluent almost at once, long before the displacement equalled the capacity of the tank. This tendency may have been increased by the irregularities of the flow, as it undoubtedly was by the variations in the temperature of the sewage. It was repeatedly observed that the turbidity of the effluents increased very much in the latter part of the afternoon, often being two or three times as great at five o'clock as at noon; and it was thought possible that the slightly increased temperature of the afternoon sewage might have caused it to come at once to the top and flow out, leaving the colder night and morning sewage in the tanks, or it may have been simply the effect of the continued higher flow during the hours in the middle of the day which brought this suspended matter to the top only after continuing for some hours.

The slowness with which the sludge was removed from the tanks undoubtedly contributed its share to the imperfect results, although it must be said that sludge was also present in Tank 4 when it was doing uniformly excellent work with a limited flow. The sludge which settled on the conical-shaped bottoms of the tanks did not of itself settle to the point of the cone, but required to be pushed down

at intervals of two or three days by a heavy weight which was pulled back by means of an attached rope. The fact that the lower plates overlapped the upper and were secured by a row of heavy projecting rivets, making ledges at every joint, may have had something to do with the failure of the sludge to slide. The filter presses, although their capacity was continually increased as improvements in details of construction and operation were effected, only removed the sludge so slowly that there was hardly a time during the whole operation of the plant when there was not sludge waiting to be pressed. At times the quantity so held became troublesome by decomposing, and on two occasions, as has already been stated, it was necessary to discharge some of it unpressed into the lake to avoid a nuisance at the works. There was always plenty of sludge on the bottoms and sides of the tanks to be washed out when the occasion was favorable.

#### SUMMARY.

In an experimental way the sewage cleansing works of the World's Columbian Exposition have served to indicate some of the peculiarities of the form of settling-tank used, and have clearly defined some forms of construction which should not be repeated.

In a practical way they succeeded in holding back from Lake Michigan thirteen hundred tons of sludge removed from the sewage treated, and containing two hundred and fifty tons of actual organic matters. They prevented the sewage from making a nuisance along the lake front such as often resulted from one of the city's sewers discharging untreated sewage just north of the grounds, and they reduced the danger of infection of the water drawn from the Hyde Park intake and supplied to the fair grounds and to the southern part of the city of Chicago.

As an object lesson to thousands of visitors they have given new ideas as to the possibility and necessity of sewage treatment and as to modern methods of securing the cleanliness of the waters on which many cities and towns are located.

## APPENDIX II.

*Showing Percentages of Total Daily Volume for the Different Hours of the Day.*

[illegible]

## APPENDIX III.

*Showing the Number of "Blows" on each Day. The actual Number of Blows is recorded, except that when they occurred at very frequent intervals for a Number of Hours in succession, the Number of Hours has been substituted for the Number of Blows.*

| DAY OF MONTH—1893. | April. | May. | June. | July. | August. | September. | October. |

| 12 " . . . . .                                      | 4.04                            | 8.65                                    | 5.98                                                 | 3.42                                          | 7.76                                                       |
| Average daily flow of sewage estimated at . . . . . | 750,000                         | 1,160,000                               |                                                      | 2,794,000                                     |                                                            |

It is seen that with the low flow in May the day sewage was being slowly forced out of the sewers all through the night. During the forenoon nothing but slightly dirty water was received, and at about noon the morning sewage first made its appearance at the works. In August, with three times as great a flow, the morning sewage was noticeable as early as eight o'clock, and at nine it had become quite concentrated. Afterward it slowly increased in strength until nine in the evening, after which the sewage was rapidly displaced by clear water, and from midnight until morning very little sewage matter was received.

## APPENDIX VI.

*Samples of Sewage and Effluent taken at Noon when the Sewage had reached its full Concentration and while the Effluent was derived from the Dilute Sewage of the Preceding Night.*

## APPENDIX IX.

*Showing Quantity, Composition and Cost of Chemicals used in Precipitation.\**

## I. SULPHATE OF ALUMINA.

[From ROBERT STEVENSON & Co., Chicago.]

Cost, in barrels, . . . . . \$47 00 a ton.

*Analysis.*

Insoluble in water, . . . . . .06 per cent.  
 Alumina, . . . . . 15.64 "  
 Ferric oxide, . . . . . .50 "  
 Sulphuric acid, . . . . . 34.88 "  
 Moisture and undetermined, . . . . . 48.92 "

## II. SULPHATE OF ALUMINA.

[From MERRIMAC CHEMICAL COMPANY, Boston.]

Cost, in bulk, . . . . . \$20 40 a ton.

*Analysis.*

Insoluble in water, . . . . . 6.11 per cent.  
 Alumina, . . . . . 13.17 "  
 Ferric oxide, . . . . . 1.31 "  
 Sulphuric acid, . . . . . 32.66 "  
 Moisture and undetermined, . . . . . 46.75 "

Taking into account the difference in analyses the first sample was twice as expensive as the second.

\* The cost includes freight to Jackson Park in each case.

## III. COPPERAS.

[From WASHBURN &amp; MOEN, Waukegan, Ill.]

Cost, in bulk, . . . . . \$13 40 a ton.

*Analysis.*

|                                      |                |
|--------------------------------------|----------------|
| Insoluble in water, . . . . .        | 0.24 per cent. |
| Ferrous oxide, . . . . .             | 25.21 "        |
| Sulphuric acid, . . . . .            | 28.50 "        |
| Moisture and undetermined, . . . . . | 46.05 "        |

## IV. CRUDE FERRIC SULPHATE.

[From JOBBINS &amp; VAN RYNEBECKE, Aurora, Ill.]

Cost, in barrels, . . . . . \$32 00 a ton.

*Analysis.*

|                                      |                 |
|--------------------------------------|-----------------|
| Insoluble in water, . . . . .        | 12.00 per cent. |
| Ferric oxide, . . . . .              | 22.76 "         |
| Sulphuric acid, . . . . .            | 45.00 "         |
| Moisture and undetermined, . . . . . | 20.24 "         |

## V. LIME.

[From CHICAGO UNION LIME COMPANY]

Cost, in barrels, \$0.60 a barrel of 200 pounds, . . . \$6 00 a ton.

*Analysis.*

|                                                  |                |
|--------------------------------------------------|----------------|
| Insoluble in acid, . . . . .                     | 0.10 per cent. |
| Alumina and ferric oxide, . . . . .              | 1.00 "         |
| Calcium oxide, . . . . .                         | 57.10 "        |
| Magnesium oxide, . . . . .                       | 38.60 "        |
| Water, carbonic acid and undetermined, . . . . . | 3.20 "         |
| Lime soluble in water, . . . . .                 | 55.01 "        |

## VI. LIME.

[From HANNIBAL LIME Co., Hannibal, Mo.]

Cost, in barrels, \$0.75 a barrel of about 170 pounds, . . \$8 80 a ton.

Cost, in bulk, \$0.22 a bushel, . . . . . 6 50 "

*Analysis.*

|                                                  |                |
|--------------------------------------------------|----------------|
| Alumina and ferric oxide, . . . . .              | 1.50 per cent. |
| Calcium oxide, . . . . .                         | 95.00 "        |
| Water, carbonic acid and undetermined, . . . . . | 3.50 "         |
| Lime soluble in water, . . . . .                 | 93.00 "        |

Even at the higher price paid for the Hannibal lime it was a much more economical lime to use on account of the much higher percentage of available lime. The magnesia present in the local lime is without value in sewage treatment; it simply adds itself to the sludge.

During the first weeks an attempt was made to apply chemicals in proportion to the flow of sewage without having any fixed schedule, but the plan proved to be too complicated, with the four sets of chemicals for the four tanks, each of which required separate regulation, particularly during those hours when it was impracticable for either myself or my assistant to closely supervise the operation, and after a little while the following arrangement was made and worked very satisfactorily: a schedule was prepared showing the quantity of alum, copperas, or ferric sulphate to be dissolved for each tank at 7.30 A.M., 3.30 and 11.30 P.M. The men on each shift commenced work half an hour earlier than these times. Each man weighed the quantities of chemicals shown by the schedule into the respective tanks used for this purpose and dissolved them in a tank full of water, using at first steam, and in the summer after the water became warmer, compressed air to thoroughly stir up the contents of the tanks. The solutions so prepared were allowed to flow into the sewage, varying the rates with changes in the flow of sewage as well as possible, but in such a way as to make the solution last through and yet be exhausted at the expiration of the eight hours' shift. The lime schedule was arranged somewhat differently. The lime was always slaked in barrel lots, and the schedule showed the hours at which lime was to be added. Each lot was made to last until the next lot was slaked, varying the flow with the flow of sewage as far as possible within that time.

A constant stream of water was kept running through the lime box in use to stir up and wash out the lime as required. Water from a tap instead of sewage was used both for this purpose and for dissolving the other chemicals, on account of the practical difficulty of regulating a small stream of sewage with the slight head available. Putting the chemicals into the sewage at four points instead of one, so reduced the quantity and the flow of water required to carry the chemicals at each point, that when sewage was used for mixing the chemicals the gates were continually becoming stopped with sewage matters. The quantity of water used for dissolving the alum, copperas and ferric sulphate was about six thousand gallons daily; the quantity used for carrying the lime may be roughly estimated at from twenty to forty thousand gallons.

The schedules of chemicals were arranged to make the quantities employed on the different shifts approximately proportional to the quantities of sewage, some allowance being made, however, for the

more dilute sewage during the night. Usually the same quantities of chemicals were used through one week, except that as a rule only half as large a quantity was required on Sunday, while on special days the quantities were increased. With copperas, as much lime was ordinarily used as would give a strong reaction with phenolphthalein in the effluent. With ferric sulphate and alum the quantity of lime used was less and was added more to give a sludge which could be easily pressed than with reference to the effluent, as sewage is sufficiently alkaline to decompose these salts without the use of lime.

Variations in the quantities of sewage necessitated very frequent changes in the chemical schedules, and the proportions of the total quantities used on the different shifts were also varied to meet changing conditions. In calculating the cost of chemicals the weights in the note books have been taken, and these weights in all cases foot up somewhat differently from the weights bought, the error usually being under 3 per cent., sometimes in one direction, sometimes in the other. During the first part of the time when Alum, I. and Lime, V. were being used, the costs were very much higher than for corresponding quantities of Alum, II. and Lime, VI. During two weeks, one ending July 14 and the other September 8, the amount of lime used was limited by the stock on hand.

\* Estimated.

## APPENDIX X.

*Distribution of Mineral Matters.*

The following table contains calculations of the quantities of mineral matters in the sewage, chemicals employed, sludge and effluent for the different periods. Without discussing in detail the method of calculation, it may be stated that it is estimated that each hundred pounds of lime employed adds one hundred and seventy pounds to the mineral matters of either the sludge or of the effluents, and that one hundred pounds of the other chemicals add fifty-three pounds in the same way.

| Mineral matter in effluent, . . . . .               | 64.4                     | 69.9                    | 89.6                     | 90.3                       | 95.8                       | 410.0  |
| Sum, . . . . .                                      | 101.6                    | 111.5                   | 145.4                    | 155.2                      | 167.7                      | 601.4  |
| Excess of matters in effluent and sludge, . . . . . | 1.9                      | 2.5                     | 5.6                      | 10.0                       | 8.9                        | 28.9   |

The excess of mineral matters in the sludge and effluent is to be attributed to the same causes as the excess of organic matters, but the discrepancy is less, owing to the small quantity of insoluble mineral matters in the sewage.

## APPENDIX XI.

*Cost of Construction and of Operation of Sewage Cleansing Works.*

The cost of construction of the sewage cleansing works was about \$55,000, of which more than \$20,000 was for the building. The approximate costs of operation for different periods are shown in the following table, in which the expenses are distributed as well as possible between the treatment of the sewage and the pressing of the sludge. The figures do not include the cost of superintendence, the cost of the chemical laboratory, or the cost of burning the sludge, which was done at an Engle crematory.

# MORTALITY REPORTS.

---

---

## SUMMARY OF THE WEEKLY MORTALITY REPORTS FROM CITIES AND TOWNS.

---

This summary comprises the returns of deaths made at the end of each week by the town clerks, city registrars and other officials having in charge the vital statistics of cities and towns.

These returns are compiled each week and published as a bulletin, one copy of which is sent to each city and town in the State.

These reports are necessarily incomplete since they are voluntary, and comprise the mortality statistics of a part of the population only, the reporting places being chiefly the cities and large towns.

The estimated population of the cities and towns contributing to the returns of 1893 was about 1,460,000, or about 60 per cent. of the total population of the State.

The data embraced in this summary are the following : —

- Average height of barometer for each week.
- Mean or daily maximum temperature.
- Mean or daily minimum temperature.
- Rainfall expressed in inches.
- Total deaths reported for each week.
- Deaths of children under five years.
- Deaths from infectious diseases.
- Deaths from consumption.
- Deaths from acute lung diseases.
- Deaths from typhoid fever.
- Deaths from diarrhoeal diseases.
- Deaths from scarlet-fever.
- Deaths from measles.
- Deaths from diphtheria and croup.
- Deaths from puerperal fever.
- Deaths from whooping-cough.
- Deaths from malarial fever.
- Deaths from small-pox.
- Deaths from erysipelas.

**Average reporting population,**

\* The figures in this column are the monthly averages for New England, being the mean of about 155 stations.

**1,458,840**

## TOTAL DEATHS.

The whole number of deaths reported for the year 1893 from the cities and towns contributing to these reports was 30,247, and the average number per week was 582. The greatest number of deaths reported in a single week was 788 in the week ending July 29, and the least number was 427 in the week ending June 24.

The weekly average number of deaths reported for each month was as follows:—

|                     |     |                      |     |
|---------------------|-----|----------------------|-----|
| January, . . . . .  | 576 | July, . . . . .      | 568 |
| February, . . . . . | 591 | August, . . . . .    | 708 |
| March, . . . . .    | 621 | September, . . . . . | 574 |
| April, . . . . .    | 622 | October, . . . . .   | 534 |
| May, . . . . .      | 595 | November, . . . . .  | 496 |
| June, . . . . .     | 479 | December, . . . . .  | 563 |

The months in which the greatest mortality was reported were March, April and August, and those in which there was the least reported mortality were June, October and November. The percentages of mortality in each of the four quarters of the year were as follows:—

|                           | ALL AGES. |              | AGES UNDER FIVE YEARS. |              |
|---------------------------|-----------|--------------|------------------------|--------------|
|                           | Numbers.  | Percentages. | Numbers.               | Percentages. |
| First quarter, . . . . .  | 7,153     | 23.65        | 2,276                  | 21.15        |
| Second quarter, . . . . . | 7,418     | 24.52        | 2,188                  | 20.34        |
| Third quarter, . . . . .  | 8,641     | 28.57        | 4,126                  | 38.35        |
| Fourth quarter, . . . . . | 7,035     | 23.26        | 2,169                  | 20.16        |
|                           | 30,247    | 100.00       | 10,759                 | 100.00       |

The death rate of reporting cities and towns was 20.74 per 1,000, the estimated population being 1,458,840.

## DEATHS UNDER FIVE YEARS.

The reported number of deaths of children under five years of age was 10,759, and the average weekly number was 207.

The greatest number reported in one week was 444 in the week ending August 19, and the least number was 123 in the week ending June 24. The ratio of the deaths of this class to the total reported mortality was 35.5 per cent., which was slightly greater than that of the preceding year (34.1 per cent.).

The average weekly number of deaths of children under five years of age by months was as follows : —

|                     |     |                      |     |
|---------------------|-----|----------------------|-----|
| January, . . . . .  | 170 | July, . . . . .      | 243 |
| February, . . . . . | 196 | August, . . . . .    | 377 |
| March, . . . . .    | 203 | September, . . . . . | 281 |
| April, . . . . .    | 177 | October, . . . . .   | 183 |
| May, . . . . .      | 178 | November, . . . . .  | 158 |
| June, . . . . .     | 148 | December, . . . . .  | 161 |

The months having the greatest number of deaths of this class were July, August and September, and those having the least number were June, November and December.

#### CONSUMPTION.

The number of reported deaths from consumption was 3,217 and the weekly average was 62. The greatest number of deaths reported from this cause in a single week was 97 in the week ending April 15, and the least number was 39 in the week ending June 24.

The average weekly number of reported deaths from this cause in each month was as follows : —

|                     |    |                      |    |
|---------------------|----|----------------------|----|
| January, . . . . .  | 70 | July, . . . . .      | 55 |
| February, . . . . . | 59 | August, . . . . .    | 61 |
| March, . . . . .    | 71 | September, . . . . . | 61 |
| April, . . . . .    | 75 | October, . . . . .   | 52 |
| May, . . . . .      | 63 | November, . . . . .  | 64 |
| June, . . . . .     | 53 | December, . . . . .  | 56 |

The months having the greatest number of deaths from this cause were March and April, and those having the least number were June and October.

The following table presents the variations from the weekly average number of deaths from this cause for the past four years : —

|                     | 1890. | 1891. | 1892. | 1893. |                      | 1890. | 1891. | 1892. | 1893. |
|---------------------|-------|-------|-------|-------|----------------------|-------|-------|-------|-------|
| January, . . . . .  | +42   | +4    | +13   | +8    | July, . . . . .      | -8    | -4    | -3    | -7    |
| February, . . . . . | +3    | -4    | -8    | -3    | August, . . . . .    | -4    | -3    | -4    | -1    |
| March, . . . . .    | +3    | -5    | -1    | +9    | September, . . . . . | -5    | -3    | -11   | -1    |
| April, . . . . .    | +1    | +4    | +7    | +13   | October, . . . . .   | -11   | +3    | -5    | -10   |
| May, . . . . .      | +1    | +6    | 0     | +1    | November, . . . . .  | -12   | -4    | -4    | +2    |
| June, . . . . .     | -3    | -2    | -5    | -9    | December, . . . . .  | 0     | +5    | -1    | -6    |

The ratio of reported deaths from consumption to the mortality reported from all causes was 106.35 per 1,000, while that of previous years was as follows:—

|                 |       |                 |       |
|-----------------|-------|-----------------|-------|
| 1886, . . . . . | 156.5 | 1890, . . . . . | 130.0 |
| 1887, . . . . . | 141.1 | 1891, . . . . . | 116.5 |
| 1888, . . . . . | 134.2 | 1892, . . . . . | 111.3 |
| 1889, . . . . . | 125.0 | 1893, . . . . . | 106.5 |

The ratio to the reporting population in 1893 was 2.20 per 1,000, as compared with 2.35 in 1892.

### ACUTE LUNG DISEASES.

The number of reported deaths from acute lung diseases (bronchitis, pneumonia, pleurisy and asthma) during the year was 4,484, and the weekly average was 86. The greatest number of deaths reported from this group of causes in a single week was 170, in the week ending April 22, and the least number 20, in the week ending September 9.

The average weekly number of reported deaths from these causes for each month was as follows:—

|                     |     |                      |     |
|---------------------|-----|----------------------|-----|
| January, . . . . .  | 116 | July, . . . . .      | 54  |
| February, . . . . . | 127 | August, . . . . .    | 29  |
| March, . . . . .    | 124 | September, . . . . . | 31  |
| April, . . . . .    | 154 | October, . . . . .   | 40  |
| May, . . . . .      | 123 | November, . . . . .  | 64  |
| June, . . . . .     | 67  | December, . . . . .  | 119 |

The months having the greatest number of reported deaths from these causes were February and April, and those having the least number were August and September.

The ratio of reported deaths from acute lung diseases to the reported mortality from all causes was 14.82 per 1,000.

The estimated death rate per 1,000 of the reporting population from these causes was 3.07, as compared with 2.82 for the previous year.

### TYPHOID FEVER.

The total number of reported deaths from this cause in 1893 was 427, and the average weekly number was 8. The greatest number reported in any single week from this cause was 19 in the week ending October 21, and the least number was 2 in the week ending April 1.

The average weekly number of deaths reported from this cause for each month was as follows :—

|                     |   |                      |    |
|---------------------|---|----------------------|----|
| January, . . . . .  | 9 | July, . . . . .      | 4  |
| February, . . . . . | 8 | August, . . . . .    | 9  |
| March, . . . . .    | 5 | September, . . . . . | 13 |
| April, . . . . .    | 6 | October, . . . . .   | 17 |
| May, . . . . .      | 5 | November, . . . . .  | 11 |
| June, . . . . .     | 5 | December, . . . . .  | 10 |

The months having the least number of deaths from this cause were March, June and July, and those having the greatest number were September, October and December.

The ratio of reported deaths from typhoid fever to the reported mortality from all causes was 14.12 per 1,000, and the ratio to the reporting population was .29, as compared with .31 in the previous year.

#### DIPHTHERIA AND CROUP.

The total number of reported deaths from diphtheria and croup in 1893 was 1,013, and the average number in each week was 20. The greatest number reported in a single week from these combined causes was 37, in the week ending October 28, and the least number was 6, in the week ending June 24.

The average weekly number of reported deaths from these causes for each month was as follows :—

|                     |    |                      |    |
|---------------------|----|----------------------|----|
| January, . . . . .  | 28 | July, . . . . .      | 16 |
| February, . . . . . | 22 | August, . . . . .    | 10 |
| March, . . . . .    | 21 | September, . . . . . | 15 |
| April, . . . . .    | 16 | October, . . . . .   | 29 |
| May, . . . . .      | 27 | November, . . . . .  | 26 |
| June, . . . . .     | 12 | December, . . . . .  | 27 |

The months having the greatest number of reported deaths from these causes were January, October and December, and those having the least number were June, August and September. The ratio of deaths from diphtheria and croup to the reported mortality from all causes was 33.49 per 1,000, and the death rate of the reporting population was .69 per 1,000, that of the previous year being .66.

## SCARLET-FEVER.

The reported deaths from scarlet-fever in 1893 were 527, and the average weekly number was 10. The greatest number of reported deaths from this cause in a single week was 21, in the week ending March 18, and the least number reported in a single week was 3, in the week ending September 9. The average weekly number reported in each month was as follows:—

|                     |    |                      |    |
|---------------------|----|----------------------|----|
| January, . . . . .  | 16 | July, . . . . .      | 7  |
| February, . . . . . | 12 | August, . . . . .    | 4  |
| March, . . . . .    | 15 | September, . . . . . | 5  |
| April, . . . . .    | 12 | October, . . . . .   | 5  |
| May, . . . . .      | 11 | November, . . . . .  | 9  |
| June, . . . . .     | 8  | December, . . . . .  | 13 |

The months having the greatest number of deaths from this cause were January and March, and those having the least number were August and October.

The ratio of deaths from this cause to the reported deaths from all causes was 17.44 per 1,000, and the death rate of the reporting population from this cause was .36 per 1,000, that of the previous year being .32.

## MEASLES.

The total number of reported deaths from measles in 1893 was 100, and the weekly average number was 2.

The greatest number in a single week was 9. There were nine weeks in which no deaths from measles were reported.

The average weekly number reported in each month was as follows:—

|                     |   |                      |   |
|---------------------|---|----------------------|---|
| January, . . . . .  | 1 | July, . . . . .      | 1 |
| February, . . . . . | 1 | August, . . . . .    | 1 |
| March, . . . . .    | 2 | September, . . . . . | 1 |
| April, . . . . .    | 2 | October, . . . . .   | 1 |
| May, . . . . .      | 7 | November, . . . . .  | 2 |
| June, . . . . .     | 3 | December, . . . . .  | 1 |

The ratio of deaths to the reported mortality from all causes was 3.31 per 1,000, and the death rate from this cause was .06 per 1,000 of the reported living population, as compared with .03 in 1892.

## DIARRHŒAL DISEASES.

The diseases included in this group are diarrhœa, dysentery, cholera morbus and cholera infantum.

From these causes combined the number of deaths reported in 1893 was 2,497, and the weekly average number was 48. The greatest number reported in a single week was 245 in the week ending August 5, and there were none reported in the week ending June 3.

The average weekly number of reported deaths from these causes in each month was as follows : —

|                     |    |                      |     |
|---------------------|----|----------------------|-----|
| January, . . . . .  | 6  | July, . . . . .      | 112 |
| February, . . . . . | 6  | August, . . . . .    | 217 |
| March, . . . . .    | 5  | September, . . . . . | 124 |
| April, . . . . .    | 8  | October, . . . . .   | 41  |
| May, . . . . .      | 6  | November, . . . . .  | 13  |
| June, . . . . .     | 12 | December, . . . . .  | 7   |

The months having the greatest number of reported deaths from these causes in 1893 were July, August and September, and those having the least were January, February and March.

The deaths from these causes in the third quarter of the year constituted 82 per cent. of the number of deaths from the same causes for the entire year. The ratio of reported deaths to the reported mortality for all causes was 82.5 per 1,000, and the death rate of the reporting population from these causes was 1.71 per 1,000, as compared with 1.66 in 1892.

### WHOOPIING-COUGH, MALARIAL FEVER, ERYSIPELAS, PUERPERAL FEVER AND SMALL-POX.

The essential statistics relating to these five diseases are embraced in the following table : —

|                            | Total Deaths<br>Reported. | Weekly<br>Average. | Ratio per<br>1,000<br>of Reported<br>Deaths from<br>All Causes. | Ratio per<br>1,000<br>of Estimated<br>Population. |
|----------------------------|---------------------------|--------------------|-----------------------------------------------------------------|---------------------------------------------------|

## REPORTS OF INFECTIOUS DISEASES.

---

For very many years laws have existed in this State requiring that notices of cases of diseases dangerous to the public health should be given to the board of health of the city or town in which they have occurred; but the vital importance of such a system of notification does not appear to have become impressed firmly upon the public mind until a comparatively recent period. It was not until 1889, in fact, that a law was enacted in England requiring such notices, and even then it was made a matter of local option except in London.

The chief advantages of a system of notification lie in the possibility which is thus given to a local board of health to determine the extent of prevalence of an epidemic or a localized outbreak, and to inquire into the local causes which have operated to produce it. The board can then act intelligently in applying the proper remedies for preventing its further spread.

In Massachusetts there can be no doubt that the law relative to notification has been productive of excellent results in the prevention of disease, especially in the cities and large towns. It has furnished the local boards of health with the necessary information relative to the origin of outbreaks of infectious disease, and in many instances enabled them to take timely steps for preventing further outbreaks. The recent law requiring local boards to keep records upon this important matter, has furnished information as to the prevalence of certain diseases in the principal cities and towns of the State. In the smaller towns it is probable that instances of failure to comply with the provisions of the statute are much more frequent than they are in cities.

Up to 1883 no definite authority was given by statute for notification to the central authority, the State Board of Health. In that year a law was enacted requiring immediate notice to be given by local boards to the State Board of Health of the occurrence of cases of small-pox.

Ten years later by the provisions of chapter 302 of the Acts of 1893, it was required that reports of all diseases dangerous to the public health should be made to the State Board of Health.

The following is the act of 1893 relative to reporting dangerous diseases to the State Board of Health:—

[CHAPTER 302 OF THE ACTS OF 1893.]

(1.) When the board of health of any city or town has had notice of the occurrence of a case of small-pox or any other disease dangerous to the public health in such city or town, such board of health shall, within twenty-four hours after the receipt of such notice, notify the state board of health of the same.

(2.) If the board of health of the city or town, in which a case of small-pox or any other disease dangerous to the public health has occurred, refuses or neglects to send a notice as required in section one, such city or town shall forfeit its claim upon the Commonwealth for the payment of any expenses which may be incurred as provided in section eighty-three of chapter eighty of the Public Statutes.

Since no definite statement was made in this act defining the term “dangerous to the public health” the Board deemed it proper, in order to relieve local authorities of uncertainty in the matter, to specify the diseases which, in the opinion of the Board, should be thus reported under the provisions of the act.

For this purpose a circular was prepared in which it was specified that, in addition to *small-pox*, the following diseases shall be considered as dangerous to the public health within the meaning of the foregoing act: *scarlet-fever, measles, typhoid fever, diphtheria, membranous croup, cholera, yellow fever, typhus fever, cerebro-spinal meningitis, hydrophobia, malignant pustule, leprosy and trichinosis.*

This circular was issued in September, 1893. Previous to that date very few returns had been received in compliance with the terms of the act.

The act was approved May 3, 1893, and the first returns to be received came from the city of Cambridge, which has sent continuous returns since May, 1893. A few more cities and towns complied with the provisions of the act during the months of June, July and August, but no large number of cities and towns made returns until a circular was prepared notifying them of the enactment of the law. This circular was issued to each city and town in

September, after which the returns came with regularity from many cities and towns.

The following is the form of the return recommended by the Board and issued by it in the form of postal cards to each local Board of Health : —

*Report of Infectious Diseases to the State Board of Health, as  
required by the provisions of Chapter 302, Acts of 1893.*

|                                                                                                                                                              |                                     |

| _____                                                                                                                                                        |                                     |
| _____                                                                                                                                                        |                                     |
| _____                                                                                                                                                        |                                     |

(Signed) \_\_\_\_\_  
Secretary or Agent of Board of Health.

*This postal card report should in all cases be signed by the Secretary or Clerk of the local Board of Health, or by the authorized Agent of the Board.  
In the blank spaces should be written the names of any of the unusual forms of infectious diseases enumerated below, if such should occur : —  
Cholera, Typhus Fever, Yellow Fever, Cerebro-spinal Meningitis, Hydrophobia, Malignant Pustule, Glanders and Trichinosis.*

The results of these notices are published each week in the Weekly Bulletin of Mortality and Infectious Diseases.

The following tables embrace the results of these returns for the fractional part of the year 1893 which elapsed after the enactment of the law : —

*Cases of Diseases dangerous to the Public Health reported by Local Boards of Health to the State Board of Health for the Fractional Year ending Dec. 31, 1893.*

|                                                                             |             |
|-----------------------------------------------------------------------------|-------------|
| Total number of reported cases of diphtheria and croup, . . . . .           | 1,109       |
| Total number of reported cases of scarlet-fever, . . . . .                  | 2,914       |
| Total number of reported cases of typhoid fever, . . . . .                  | 1,525       |
| Total number of reported cases of measles, . . . . .                        | 1,503       |
| Total number of reported cases of small-pox, . . . . .                      | 35          |
|                                                                             | <hr/> 7,086 |
| Additional cases of small-pox reported under the statute of 1883, . . . . . | 8           |
|                                                                             | <hr/> 7,094 |
| Total, . . . . .                                                            | 7,094       |

The following table shows the distribution of these cases by months of the year.

Reports were not generally forwarded to the State Board until after the public notice was given in September, which accounts for the small number before that date.

*Reports of Dangerous Diseases Classified by Months.*

| 1893.                | Diphtheria<br>and Croup. | Scarlet-<br>fever. | Typhoid<br>Fever. | Measles. | Small-pox. |

Total (including small-pox), . . . . . 7,094

\* These were cases of small-pox reported under the statute of 1883 by cities and towns which made no reports of other diseases under the law of 1893.

The foregoing table shows that exactly one-half of the local boards of health in the State have complied with the law, and have sent returns to the State Board of Health of the cases of disease "dangerous to the public health" reported to them, leaving one-half of the towns from which no reports whatever have been received.

These 175 cities and towns reporting, however, constitute much more than one-half the population, since in this list are embraced all of the cities except Holyoke.

The following classified list contains the names of those towns whose boards of health failed to comply with the terms of the statute of 1893, no reports having been forwarded by them to the State Board of Health of the occurrence of cases of infectious or dangerous diseases. The list of towns is classified according to population.

*I. Cities.*

Holyoke.

*II. Towns having Populations of More than 5,000 in Each.*

|             |                |                    |
|-------------|----------------|--------------------|
| Adams,      | Framingham,    | Revere,            |
| Andover,    | Hyde Park,     | Spencer,           |
| Blackstone, | Middleborough, | Southbridge. — 10. |
| Clinton,    |                |                    |

*III. Towns having a Population of Over 1,000 but Less than 5,000 in Each.*

|                   |                  |                  |
|-------------------|------------------|------------------|
| Abington,         | Hadley,          | Petersham,       |
| Acton,            | Hanover,         | Provincetown,    |
| Ashfield,         | Harvard,         | Rehoboth,        |
| Avon,             | Harwich,         | Royalston,       |
| Barnstable,       | Holbrook,        | Sandwich,        |
| Barre,            | Holden,          | Sheffield,       |
| Belchertown,      | Holliston,       | Shelburne,       |
| Bellingham,       | Hopedale,        | Sherborn,        |
| Billerica,        | Hopkinton,       | Shirley,         |
| Braintree,        | Hubbardston,     | Shrewsbury,      |
| Buckland,         | Hudson,          | Southampton,     |
| Canton,           | Lanesborough,    | South Hadley,    |
| Charlton,         | Lee,             | Southborough,    |
| Chatham,          | Lenox,           | Sterling,        |
| Chester,          | Longmeadow,      | Stockbridge,     |
| Cohasset,         | Manchester,      | Stoughton,       |
| Colrain,          | Marshfield,      | Sudbury,         |
| Dartmouth,        | Mattapoietts,    | Sutton,          |
| Deerfield,        | Medfield,        | Swansea,         |
| Dennis,           | Merrimac,        | Templeton,       |
| Dudley,           | Milton,          | Tisbury,         |
| Duxbury,          | Nantucket,       | Walpole,         |
| East Bridgewater, | Needham,         | Wellesley,       |
| Easton,           | Newbury,         | Wellfleet,       |
| Fairhaven,        | New Marlborough, | West Brookfield, |
| Falmouth,         | Northborough,    | Westport,        |
| Freetown,         | Northbridge,     | Wilbraham,       |
| Georgetown,       | Norton,          | Williamsburg,    |
| Granville,        | Norwell,         | Wilmington,      |
| Great Barrington, | Orleans,         | Wrentham. — 91.  |
| Groveland,        |                  |                  |

*IV. Towns having Less than 1,000 Inhabitants in Each.*

|              |                   |                    |
|--------------|-------------------|--------------------|
| Alford,      | Goshen,           | North Reading,     |
| Ashby,       | Gosnold,          | Otis,              |
| Becket,      | Hamilton,         | Pelham,            |
| Berkley,     | Hancock,          | Peru,              |
| Berlin,      | Hawley,           | Phillipston,       |
| Bernardston, | Heath,            | Plainfield,        |
| Blandford,   | Holland,          | Plympton,          |
| Boxborough,  | Lakeville,        | Prescott,          |
| Boxford,     | Leverett,         | Princeton,         |
| Boylston,    | Leyden,           | Richmond,          |
| Burlington,  | Lynnfield,        | Rowe,              |
| Carver,      | Marion,           | Russell,           |
| Charlemont,  | Mashpee,          | Rutland,           |
| Chilmark,    | Mendon,           | Savoy,             |
| Clarksburg,  | Millis,           | Southwick,         |
| Cummington,  | Monterey,         | Sunderland,        |
| Dana,        | Montgomery.       | Tolland,           |
| Dunstable,   | Monroe,           | Truro,             |
| Eastham,     | Mount Washington, | Tyngsborough,      |
| Enfield,     | Nahant,           | Tyringham,         |
| Florida,     | New Ashford,      | Washington,        |
| Gay Head,    | New Braintree,    | Wendell,           |
| Gill,        | New Salem,        | Whateley,          |
| Granby,      | Norfolk,          | Worthington. — 73. |
| Greenwich,   |                   |                    |

A review of this classified list leads to some conclusions as to the causes of the failure of so large a number to comply with the provisions of the statutes.

In the first place, the ratio of the population of the cities and towns failing to report in each of the foregoing classes as compared with the total population of the towns of each class shows that the cities and large towns have complied with the provisions of the act much more generally than the small towns.

In Class I., the cities, Holyoke is the only city failing to comply, and its population, by census of 1890, constitutes but 2.5 per cent. of the population represented in Class I.

In Class II. the population of the ten towns failing to report was 25.7 per cent. of the total population of the towns of that class.

In Class III. the population of the ninety-one towns failing to report was 48 per cent. of the total population of the towns of that class.

In Class IV. the population of the seventy-three towns failing to report was 75 per cent. of the total population of the towns of that class.

This great difference between the action of the authorities of cities and of small towns in this matter suggests two definite reasons for the considerable degree of non-compliance with the terms of the statute.

1. The non-existence of separate local boards of health in small towns having an organization for sanitary purposes only. An inquiry of the State Board made a few years since showed that boards of health independent of the selectmen existed in only one-half of the towns in the State. This being the case, the selectmen acting as boards of health are largely interested in matters of an economic or administrative character not closely related to the public health, and as a consequence matters pertaining to the health of towns are much neglected, and among them, undoubtedly, the reporting of cases of infectious diseases.

Many attempts to remedy this defect by legislative action have been made in past years, but with little success.

2. As a matter of fact infectious diseases do not prevail in sparsely settled populations to so great an extent as among the densely settled suburban districts, so that there were undoubtedly some of the very small towns in which none of the specified diseases occurred during the year. This fact is brought out very clearly in the twenty-third report of the Board (1891), wherein is shown the relation of the mortality from eight different diseases, most of them of the infectious class, to the density of the population.

While the mortality does not necessarily represent the prevalence of disease it bears a very close relation to it. In that report it was shown that for a period of twenty years (1871-90) there were two towns in the State in which there had been no deaths from diphtheria and croup, fifteen towns in which there had been no deaths from scarlet-fever, one town in which there had been no deaths from typhoid fever, 183 towns in which there had been no deaths from small-pox and ninety-five towns in which there had been no deaths from measles.

# FOOD AND DRUG INSPECTION.

---

---

## FOOD AND DRUG INSPECTION.

---

The following report comprises the work of the Board for the year ending Sept. 30, 1893, in the inspection of food and drugs.

The force employed in this department of work was the same as that of the previous year, and consisted of the following :—

|                             |           |                           |
|-----------------------------|-----------|---------------------------|
| Dr. CHARLES P. WORCESTER,   | . . . . . | <i>Analyst.</i>           |
| Prof. CHARLES A. GOESSMANN, | . . . . . | <i>Analyst.</i>           |
| Mr. ALBERT E. LEACH,        | . . . . . | <i>Assistant Analyst.</i> |
| JOHN H. TERRY,              | . . . . . | <i>Inspector.</i>         |
| JOHN F. McCAFFREY,          | . . . . . | <i>Inspector.</i>         |
| HORACE F. DAVIS,            | . . . . . | <i>Inspector.</i>         |

The work of the Board in this department has been conducted during the year in the laboratory at 994 Washington Street, Boston, temporarily occupied for this purpose until the new laboratory in the State House Extension is completed.

The whole number of samples of food and drugs examined during the year was 6,409, making the whole number examined 53,573 for the entire period since the enactment of the general food and drug acts in 1882. This number (6,409) was greater than that of any previous year.

The following summary embraces the work done during the year :—

|                                                            |           |       |
|------------------------------------------------------------|-----------|-------|
| Number of samples of milk examined,                        | . . . . . | 8,078 |
| Number of samples above standard,                          | . . . . . | 1,545 |
| Number of samples below standard,                          | . . . . . | 1,528 |
| Percentage of adulteration or deficiency,                  | . . . . . | 49.7  |
| Number of samples of other kinds of food (not milk),       | . . . . . | 8,009 |
| Number of samples above standard,                          | . . . . . | 2,637 |
| Number of samples below standard,                          | . . . . . | 372   |
| Percentage of adulteration,                                | . . . . . | 12.8  |
| Number of samples of drugs examined,                       | . . . . . | 827   |
| Number of samples of good quality,                         | . . . . . | 228   |
| Number of samples adulterated, as defined by the statutes, | . . . . . | 99    |
| Percentage of adulteration,                                | . . . . . | 30.8  |
| Total examinations of food and drugs,                      | . . . . . | 6,409 |
| Total examinations of good quality,                        | . . . . . | 4,410 |
| Total examinations not conforming to the statutes,         | . . . . . | 1,999 |
| Percentage of adulteration,                                | . . . . . | 31.2  |

## STATISTICAL SUMMARY.

FOOD AND DRUG INSPECTION (1883-1893).

| SUMMARY.                                                                  | YEARS.     |            |            |            |            |            |  |
|---------------------------------------------------------------------------|------------|------------|------------|------------|------------|------------|--|
|                                                                           | 1883.      | 1884.      | 1885.      | 1886.      | 1887.      | 1888.      |  |
| Number of samples of milk examined, . . . . .                             | 218        | 1,123      | 2,219      | 2,086      | 3,081      | 2,825      |  |
| Number of samples above standard, . . . . .                               | 35         | 347        | 1,297      | 1,323      | 1,900      | 1,706      |  |
| Number of samples below standard, . . . . .                               | 183        | 776        | 922        | 762        | 1,181      | 1,120      |  |
| Percentage of adulteration, . . . . .                                     | 83.9       | 69.1       | 41.7       | 36.5       | 38.3       | 39.6       |  |
| Number of samples of other kinds of food (not milk), . . . . .            | 477        | 839        | 1,552      | 1,353      | 1,789      | 2,079      |  |
| Number of samples of good quality, . . . . .                              | 328        | 432        | 863        | 863        | 1,203      | 1,690      |  |
| Number of samples adulterated, as defined by the statutes, . . . . .      | 149        | 407        | 689        | 490        | 586        | 389        |  |
| Percentage of adulteration, . . . . .                                     | 31.2       | 48.5       | 43.1       | 36.2       | 29.4       | 19.2       |  |
| Number of samples of drugs examined, . . . . .                            | 603        | 682        | 1,007      | 898        | 550        | 802        |  |
| Number of samples of good quality, . . . . .                              | 357        | 431        | 571        | 463        | 400        | 634        |  |

| Expense of collection, examination and prosecution, per sample, . . . . . | 1 89        | 1 67        | 1 89        | 1 80        | 1 63        | 1 77        |

It would be manifestly impossible from the statistics presented in the foregoing table to form a definite conclusion either in relation to the extent of adulteration of food which exists in Massachusetts or of its relative prevalence when the same statistics are compared with those of other countries conducting a similar line of work.

The reasons for the very marked contrast between the results reported by the British analysts and those of Massachusetts are stated in the last Report of the Board (24th report, p. 608), and one of these reasons appears to be shown more clearly in the present report wherein the general table of statistics has been rearranged in such a manner as to present the ratio of adulteration of "other samples of food," not including milk.

To what extent the legal standard of milk in Massachusetts affects the ratio of adulteration, as published in the foregoing table, may be shown by the following statement.

Out of 2,235 samples of milk taken by the inspectors of the Board in the years 1886-1889, the total solids of which were known, and all of which contained less than 13 per cent. of solids, 1,504 or 67.3 per cent. contained from 12 to 13 per cent. of solids. Nearly all of these and many more would, under the standards of most countries which have adopted a standard, have been deemed to be milk of good standard quality, since the standard in most countries is 11.50 of total solids. But in Massachusetts all of this number, except those which were collected in the months of May and June, must be reckoned as adulterated milk. The effect of this statutory provision upon the published ratio of adulteration consequently gives to our published statistics an unfavorable showing, which at the first glance might be easily misconstrued. The statistics presented in Dr. Worcester's report for the present year still further confirm this statement.

As a matter of fact, however, actual or intentional adulteration of this most important article of food is much less common than it was found to be at the beginning of the period of active enforcement of the laws relating to food and drug inspection.

The continuous work of the Board and the marked improvement in local inspection in cities have effected a marked change, which nothing but vigilant and continuous supervision could have accomplished.

*What is Adulterated Milk?*

The high percentages of samples of milk which are shown by the continuous reports of the Board to be below the legal standard of 13 per cent. of solids make it necessary to make an occasional statement of the cause.

The term "adulterated milk," under the statutes of Massachusetts, may signify milk which is simply below the legal standard of 13 per cent. of solids and nothing more, or, in other words, a natural milk, just as produced by the cow, having no other disqualification except its deficiency in total solids. The "percentage of adulteration" reported by the Board in its monthly bulletins is largely made up of this class of samples.

The second form of "adulterated milk" consists of milk which has been subjected to certain alterations by human interference. These are chiefly the addition of water, the removal of cream, the addition of coloring matter and of substances employed to preserve the milk from souring.

This second class is very much smaller in number than the former class. It is not practicable to separate the two classes and to draw an exact line between them, but it is certain that the ratio of the class of samples intentionally adulterated is very much less than it was before active measures were taken for the suppression of such conditions.

In 1884 the Board made a large number of examinations of natural milk, the samples in all cases being collected by inspectors who witnessed the milking. From the results of these analyses it would be safe to say that out of 100 samples taken at random from 100 animals throughout the different dairies in the State under varying conditions of breed, of age, time of year and methods of feeding, about thirty would prove to be below the legal standard of 13 per cent. of solids.

Among this 30 per cent. of animals the ratio of Holstein cows would probably be greater than the ratio of such cows among the 70 per cent. whose milk is found to be above the legal standard.

Very careful attention has been given to this subject in other countries, where the subject of milk inspection is deemed of very high importance, both in its sanitary and in its economic relations.

In a recent article in the *Zeitschrift für Fleisch und Milch Hygiene*, Dr. Martiny states that the percentage of the various constituents of milk to be used as a standard must be determined by the average percentage found in a given district, since this may vary somewhat. Milk in North Germany is not quite so rich in solids as that of South Germany, and in the former it shows an average of 3.3 per cent. of fat in 12 per cent. of dried solids, with a specific gravity of 1031.5, while in the latter the average solids are 12.4 per cent. and the fat 3.5.

The same writer states his belief that the percentage of fats may be increased to more than 4 per cent. in a total of 13 or 14 per cent. of solids by appropriate feeding.

The methods of feeding employed in many of the dairies which furnish the milk supply of our large cities are those which are intended to secure an increased quantity of milk at the expense of its quality, and the selection of breeds of cows whose milk is notoriously poor in quality acts in the same direction of impoverishing the quality of the milk.

In commenting upon the difficulty of subjecting to inspection the entire milk supply of a city at frequent intervals, Martiny concludes that—

1. The sale of milk should only be allowed by officially designated dealers, and in order to facilitate frequent inspection he suggests the limitation of the number of vendors of milk as is done in England and in Italy.

2. Dealers should give evidence of an intelligent knowledge of the requirements necessary for the sale of pure milk both from a sanitary and from an economic point of view.

3. Milk inspection should not be confined to market milk but should extend to the dairies.

4. In every city a well-equipped laboratory should be maintained for the scientific examination of milk.

It is gratifying to know that since the enactment of the general statute of 1882 (chap. 263), and the work which has followed during the ten years or more which have elapsed, very much more attention has been given to milk inspection by local authorities. Several of the principal cities of the State employ the services of trained inspectors who devote either the whole or a considerable portion of their time to the careful analysis of milk by laboratory

methods, and the number of such cities which find it to be for their interest to employ a trained inspector is gradually increasing.

The report of the analyst also shows that the artificial coloring of milk, once quite a common practice in the large cities, is now very rarely found, the vigorous warfare against this objectionable form of adulteration having practically suppressed it.

Among the examinations of milk reported by the analyst special attention is called to the report upon condensed milk, an article which is now largely used and has a wide field of usefulness as a convenient form of food for special purposes.

#### FOOD, OTHER THAN MILK.

In the examination of other kinds of food during the year special attention has been given to the examination of the most important and widely used of all foods — bread; and also of cheese, another valuable article of nutriment.

The points of interest noted in regard to bread are the weight of loaves, the percentage of water and of solids, the per cent. of ash in terms of solids, the acidity and the price charged for each loaf.

The average weight of loaves was found to be 404 grammes, or  $13\frac{1}{2}$  ounces.

The per cent. of moisture was quite uniform, in most instances being about 42 or 43 per cent. of the weight of the loaf, leaving 57 or 58 per cent. of solids.

The price was quite uniformly five cents per loaf, rarely four cents, for loaves of ordinary size and weight.

No adulterations are mentioned by the analyst, and at the low price of flour in the United States the adulteration of flour or of bread is of extremely rare occurrence.

The examination of samples of cheese showed a fairly uniform quality and price, the latter being at sixteen cents per pound.

Omitting four samples of special sorts, the average total solids were found to be 66.3 per cent., the fat 35 per cent., the solids, not fat, 31.3 per cent., and the water 33.6 per cent.

The following tables present the usual statistics relative to the notices sent by the Board to parties (usually retailers) from whom samples of adulterated food or drugs have been obtained during the year : —

## PROSECUTIONS.

In the last report a condensed summary of the prosecutions conducted by the Board for the entire period since the enactment of the food and drug statutes was presented. The same table is herewith published, together with the results of the prosecutions of the year ending Sept. 30, 1893:—

*Number of Complaints Entered in Court.*

| YEAR.             | Food<br>not including<br>Milk. | Drugs. | Milk. | Total. | Convictions. | Fines Imposed. |
|-------------------|--------------------------------|--------|-------|--------|--------------|----------------|
| 1883, . . . . .   | —                              | 5      | 4     | 9      | 8            | —†             |
| 1884, . . . . .   | 2                              | 1      | 45    | 48     | 44           | —†             |
| 1885,* . . . . .  | 50                             | 1      | 68    | 119    | 103          | —†             |

| 1889, . . . . .   | 74                             | —      | 66    | 140    | 124          | 3,889 00       |
| 1890, . . . . .   | 78                             | —      | 24    | 102    | 96           | 3,919 00       |
| 1891, . . . . .   | 96                             | 5      | 49    | 150    | 135          | 2,668 00       |
| 1892, . . . . .   | 52                             | 12     | 72    | 136    | 123          | 3,661 70       |
| 1893, . . . . .   | 26                             | 3      | 67    | 96     | 92           | 2,476 00       |
| Totals, . . . . . | 440                            | 27     | 482   | 949    | 865          | 18,655 70      |

\* To May 1, 1886.

† Four months only.

‡ No record kept.

Ratio of convictions to complaints, 91.1 per cent.

NOTE. — All complaints entered before May 1, 1886, were under the direction of the Board of Health, Lunacy and Charity, and all after that date were under the direction of the State Board of Health.

Under the provisions of chapter 289 of the Acts of 1884, which require the Board to report annually to the Legislature the "number of prosecutions made under" the food and drug acts, "and an itemized account of all money expended in carrying out the provisions thereof," the following report was transmitted to the General Court in January, 1894:—

OFFICE OF THE STATE BOARD OF HEALTH,  
13 BEACON STREET, BOSTON, JANUARY, 1894.

*To the Honorable Senate and House of Representatives of the Commonwealth of Massachusetts, in General Court assembled.*

The following summary is made in compliance with the provisions of chapter 289, section 2, of the Acts of 1884, requiring the State Board of Health to "report annually to the Legislature the number of prosecutions made under chapter 263 of the Acts of 1882, and an itemized account of all money expended in carrying out the provisions thereof."

The whole number of prosecutions made by authority of the Board against offenders, under the provisions of the food and drug acts, for the year ending Sept. 30, 1893, was 96.

The cities and towns in which the articles were sold, and in respect to which complaints were entered in court, the character of the articles found to be adulterated, or fraudulently sold, the dates of the trials and their result, are presented in the following table:—

### MILK AND MILK PRODUCTS.

#### *Complaints Entered for Fraudulent Sales of Milk.*

| Total, . . . . .                                                                                       | 96 cases. |

## SUMMARY.

The whole number of complaints entered by the State Board of Health in the courts of the Commonwealth against parties for violation of the acts relating to food and drug inspection was 96. In 92, or 95.8 per cent. of these, the parties were convicted. Four were discharged, either in the lower or in the upper courts.

Of the foregoing cases, 61 were for violation of the laws relating to milk adulteration, of which number 60 resulted in conviction.

Nearly all of the cases entered for violation of the statutes relating to the sale of milk were entered under the statute which provides that milk offered for sale shall be of good standard quality, the standard being defined by law.

Six complaints were entered under the oleomargarine laws, each of which resulted in conviction.

There were also twenty-six complaints for fraudulent sales of other articles of food, in all of which except two the parties were convicted. In one of these, a complaint for fraudulent sale of maple syrup, it was claimed that the crate or wholesale package was marked with the word "compound," although the retail package had no such mark to indicate the character of its contents. This is only one of many instances which illustrate the difficulties which are liable to arise under the provision by which certain articles may be sold of an inferior quality, "provided that the same are not injurious to health, and are distinctly labelled as mixtures or compounds."

The articles of food embraced in the foregoing list were the following:—

Maple syrup, 3 cases; maple sugar, 2; honey, 1; coffee, 6; molasses, 3; cassia, 1; cloves, 2; pepper, 3; mustard, 3; cream of tartar, 2.

Of the samples of drugs which were the cause of complaints at court, one case was for refusal to furnish samples to an inspector; another was for a sale of a poisonous cosmetic; and the other was for a sale of McMunn's Elixir, which was not properly marked with a poison label, in compliance with the Statute of 1888 (chapter 209).

The standard of whole milk in Massachusetts is 13 per cent. of *solid* residue, except in the months of May and June, when it is 12

per cent. The following list presents the total solids in the samples of milk upon which complaints in court were founded : —

|      |       |       |       |       |
|------|-------|-------|-------|-------|
| 4.72 | 9.80  | 10.33 | 10.70 | 11.15 |
| 8.25 | 9.82  | 10.40 | 10.73 | 11.16 |
| 8.48 | 9.82  | 10.40 | 10.75 | 11.20 |
| 8.85 | 9.95  | 10.45 | 10.79 | 11.30 |
| 9.15 | 10.02 | 10.50 | 10.80 | 11.35 |
| 9.29 | 10.21 | 10.50 | 10.94 | 11.48 |
| 9.31 | 10.21 | 10.55 | 11.00 | 11.48 |
| 9.35 | 10.25 | 10.56 | 11.04 | 11.52 |
| 9.44 | 10.26 | 10.60 | 11.12 | 11.74 |
| 9.56 | 10.26 | 10.63 | 11.12 | 13.33 |

The total number of samples of food and drugs examined during the year was as follows : —

|                                   |       |
|-----------------------------------|-------|
| Milk, . . . . .                   | 3,224 |
| Other articles of food, . . . . . | 3,009 |
| Drugs, . . . . .                  | 327   |
|                                   | <hr/> |
| Total, . . . . .                  | 6,560 |

|                                                              |             |
|--------------------------------------------------------------|-------------|
| Total expenses of collection, examination and prosecution, . | \$10,454 11 |
| Average expense per sample collected, . . . . .              | 1 59        |

### FINES.

The amount of the fines paid into the treasuries of counties, cities and towns under the provisions of the general and special laws relative to the inspection of food and drugs was as follows : —

*Fines paid for Violation of the Food and Drug Acts, upon Cases entered for the Year ending Sept. 30, 1893.*

|                                                                                |            |
|--------------------------------------------------------------------------------|------------|
| Under the provisions of the laws relating to milk and milk products, . . . . . | \$1,991 00 |
| Under the provisions of laws relative to other articles of food, . . . . .     | 459 00     |
| Under the provisions of laws relative to drugs, . . . . .                      | 26 00      |
|                                                                                | <hr/>      |
| Total, . . . . .                                                               | \$2,476 00 |

## EXPENDITURES

*Under the Provisions of the Food and Drug Acts during the Year ending Sept. 30, 1893.*

|                                                 | FOR THE ENFORCEMENT OF THE STATUTES<br>RELATING TO FOOD AND DRUG<br>INSPECTION. |                                                  |

## REPORT OF DR. C. P. WORCESTER, ANALYST.

Dr. S. W. ABBOTT, *Secretary of the State Board of Health.*

DEAR SIR:—I have the honor to present my report on the analysis of food and drugs for the year ending Sept. 30, 1893.

The work during this year has been done in the room rented by the Board for the purpose, at 994 Washington Street. The laboratory has proved sufficient for the ordinary routine work, but for any investigation involving special apparatus its resources are too limited. The routine analysis this year has been similar to that of previous years.

### MILK.

| Towns, . . . . .               | 639                            | 375                | 264                | 41.3                            | 9.19              | 2                              |
| Suspected producers, . . . . . | 482                            | 169                | 323                | 67.0                            | 4.72              | —                              |
| Miscellaneous, . . . . .       | 21                             | 10                 | 11                 | 52.4                            | —                 | —                              |
| Total milks, . . . . .         | 3,073                          | 1,545              | 1,528              | 49.7                            | 4.72              | 15                             |

The percentage of samples below standard is 49.7, practically the same as that of last year, which was 48.2 per cent.

The relative advantages of the various processes for the analysis of milk have been discussed at great length in the many text-books and in meetings of analysts the world over. For the purpose of determining the total solids there is no readier method that is reasonably accurate than the evaporation of a weighed quantity of milk over steam in flat-bottomed platinum capsules. The determination of the fat by benzine extraction of this dry residue has proved an

It will be seen that under a standard of 13 per cent. throughout the entire year the ratio of samples below the standard would be 61.2 per cent., while with a 12 per cent. standard for the year the ratio would be only 16.3 per cent., so that the relative showing for the year is largely dependent on legislative enactment.

The following tables show the sources of the various samples of milk examined, apportioned among the cities, towns and suspected producers :—

*Milk from Cities.*

The comparison of the quality of samples by months is of some interest in view of the efforts made to reduce the standard during the spring and summer months.

For this purpose the following tables have been prepared, showing the percentage of adulteration during the months of the preceding as well as of the present year, with both 12 and 13 per cent. assumed as a standard through the whole year : —

QUALITY OF MILK BY MONTHS. YEAR ENDING SEPT. 30, 1892.

*Condensed Milk.*

Samples of condensed milk and so-called "evaporated cream" were analyzed for total solids and fat with the following results, the fat being obtained by benzine extraction : —

| INSPECTORS' NUMBER. | Brand.                 | Character of Sample. | Per Cent. Solids. | Per Cent. Solids not Fat. | Per Cent. Fat. | Per Cent. Water. |
|---------------------|------------------------|----------------------|-------------------|---------------------------|----------------|------------------|

*Cheese.*

Seventy-three samples of cheese have been examined and no case of fraudulent adulteration has been found. A series of forty-one samples were obtained at different times from the poorer quarters of Boston, and were analyzed immediately after purchase, before any appreciable loss of water by evaporation could take place, with the following results : —

\* Skimmed milk cheese.

† Neufchatel cheese.

‡ Cream cheese.

§ Average is exclusive of last four samples.

It will be noticed that with few exceptions the uniform retail price of whole-milk cheese was found to be sixteen cents per pound. The exceptions were the skimmed-milk cheeses and remnant lots of poor quality which were cheaper and the extra cream cheeses which were more expensive. This means two-thirds of a pound of milk solids for sixteen cents, or one pound for twenty-four cents. Now, twenty-four cents will buy at retail, as a rule, four quarts of standard milk, which contain approximately one pound of milk solids. Weight for weight, then (water excluded), cheese and milk are sold practically at the same rate. It should be added, however, that nearly one-third of the milk solids is sugar, a much cheaper element of food than the fat and proteids which are in greater proportion in cheese. The percentage of fat determined by the Babcock process in terms of solids averaged 53 per cent., a somewhat high ratio. Of standard milk the fat is 28 per cent. in terms of the solids, the smaller ratio being due chiefly to the excess of sugar in the milk solids.

#### *Butter.*

In but one instance has the fraudulent substitution of oleomargarine for butter been found. Four hundred and seventeen samples of butter have been analyzed and twenty-four of oleomargarine.

#### *Bread.*

Fifty-nine samples of bread, chiefly of cheap white bread, were collected from the poorer classes of bakeries and grocers' shops in order to ascertain what sort of bread is furnished to the poorer classes who usually depend on the "corner grocery" for their supply.

Inspection showed, as a rule, loaves which were not far from the standard "home-baked family loaf." They showed, as a rule, a thorough baking, though there were not a few exceptions to this rule; they were well "raised," had a good crumbling fracture, were not tough and soggy, nor, on the other hand, were they over-raised, with a dry and spongy texture. The majority had the sweet, agreeable odor and taste described as the "nutty flavor" characteristic of a well-made loaf. In a number of instances, however, there was distinctly perceptible a musty flavor, amounting in some cases to a downright sour odor and taste. This sourness seems, at least in part, to be due to a bacterial growth attended by

the production of lactic acid or of acid salts. At what stage in the process of manufacture this incipient decomposition has taken place it is impossible to determine without a careful investigation of each step in the process of making every loaf.

The souring of bread may usually be traced to poor materials or to uncleanness in the manufacture. Chief among the unsound materials which may contribute toward this sourness are usually noted damaged flour and decomposing yeast. So far as has been investigated the use of unsound flour is not practiced in this part of the country. The yeast generally used is of excellent quality. It is a stiff, smooth mash, put up usually in small tin-foiled cakes, and kept in a cool place. Under the microscope this mash is seen to be composed of about equal parts of potato or corn starch and yeast spores. It has a distinct yeasty odor, and but rarely is it strongly acid in reaction. To the almost universal use of good sweet yeast of this variety in the small bakeries is doubtless due no small share in the great improvement in quality of the common baker's loaf of today as compared with that of ten or more years ago.

A vigorous, pure yeast which will "raise" quickly is a great preventive against sour bread, for not only is it comparatively free from the germs and products of lactic acid decomposition, but by doing its work quickly it enables the baker to check the fermentation or "raising" process before the lactic acid or sour decomposition is reached.

The degree of sourness of the samples of bread examined has been roughly measured and compared by titrating or neutralizing 10 grammes of the crumb, rubbed up with water, with a decinormal soda solution. To neutralize the acidity of 10 grammes of the normally sweet loaf an average of 2 cubic centimeters of the soda solution was required. This would correspond to 0.72 grammes of lactic acid per loaf of an average weight of about 400 grammes. The loaf exhibiting the maximum sourness or acidity required 10 cubic centimeters per 10 grammes of bread corresponding to 11.61 grammes of lactic acid per loaf of 1,291 grammes.

The so-called black bread (rye bread), which finds a ready sale among our foreign population, is notably sour and heavy, and apparently its sourness is valued by this class. A sour bread is undesirable, not only because it is unpalatable but also because of the bacterial processes of decomposition which this acidity indicates, and which may seriously interfere with digestion.

Average weight of loaf of white bread is 404 grammes. Usual price is five cents. Average percentage of water of crumb is 42 per cent.

*Spices.*

The microscopic examination of over 1,400 samples of ground spices resulted in the discovery of 189, or 14 per cent. of adulterated samples.

*Allspice.*

Adulteration, 5 per cent. Adulterants found were wheat, corn, ginger and nut shells.

*Cassia.*

Adulteration, 7 per cent. Adulterants found were ginger, bark of some variety, wheat, pease, sawdust and nut shells. The worst specimen contained 75 per cent. of wheat.

*Cayenne.*

Adulteration, 38 per cent. Adulterants found were corn, wheat, ginger, nut shells and turmeric. The worst specimen contained 90 per cent. of wheat, corn, turmeric and cocoanut shells. Many of these samples were purchased as "capsicum" from drug stores, and in these instances the percentage of adulteration was higher than the average.

*Cloves.*

Adulteration, 13 per cent. Adulterants found were corn, wheat, allspice, nut shells, pease, ginger, pepper, charcoal, dirt, turmeric and clove stems. The worst specimen contained 70 per cent. of nut shells, pease and ginger.

*Ginger.*

Adulteration, 7 per cent. Adulterants found were corn, wheat, rice and turmeric. The worst specimen contained 40 per cent. of corn and turmeric.

*Mace.*

The only adulteration found was the apparently accidental admixture of other spices in one instance.

*Mustard.*

Adulteration, 27 per cent. Adulterants found were wheat, corn, rice, cayenne, mustard hulls, tapioca and turmeric, the latter being added for color both in the ground form and in the form of an extract. The worst specimen contained but a small trace of mustard, the other constituents being the first four of the above-named adulterants, colored with turmeric.

*Nutmeg.*

No adulteration found.

*Pepper.*

Adulteration, 11 per cent. Adulterants found were wheat, buckwheat, corn, sawdust, cayenne, nutshells and charcoal. The worst specimen contained 90 per cent. of wheat, buckwheat and cayenne.

*Baking Powder.*

Of eight brands of baking powder examined, six contained alum.

*Canned Goods.*

Of nineteen samples of canned goods of various kinds, none were found to contain any harmful preservative or metallic poison.

*Chocolate.*

No adulteration was found in the five samples submitted.

*Confectionery.*

Of the fifty-nine samples examined, all but two were composed of edible and non-injurious constituents, such as cane sugar, glucose, and wheat, corn and potato starch. Two samples contained paraffin in considerable amount and turpentine, which was added doubtless under the name of "Essence of Lemon."

*Coffee.*

Adulteration, 30 per cent. Adulterants found were chicory, pease, wheat, wood, charcoal and dried grains composed of ground pea hulls and molasses. The worst case of adulteration contained 50 per cent. of pease and chicory, while a "compound coffee" was found to contain no coffee whatever. A coffee substitute and adulterant was found to consist of small brown pellets of about the size of coffee beans, but composed of wheat mash, mixed with a red oxide of iron for a color, and roasted.

*Cream of Tartar.*

Adulteration, 3 per cent. Adulterants found were gypsum, corn starch and phosphate of calcium. The adulteration of cream of tartar is now comparatively rare. The worst sample contained 75 per cent. of calcium phosphate and corn, while a "compound cream of tartar" was found to contain no cream of tartar whatever.

*Honey.*

Adulteration, 14 per cent. The only adulterant found was glucose syrup, which was found in varying amounts up to 40 per cent. The analysis of honey, sugars and syrups is made by means of the polariscope.

*Molasses.*

Adulteration, 11 per cent. The only adulterant found was glucose syrup, which was present in one instance to the extent of 40 per cent.

*Maple Syrup.*

Adulteration, 43 per cent. Adulterants found were cane sugar other than maple and glucose. The worst specimen was a so-called "Vermont Maple Syrup," containing 58 per cent. of glucose syrup.

*Maple Sugar.*

Adulteration, 34 per cent. The adulterant found was a crude molasses sugar, which chemically is nearly identical with maple sugar, but whose flavor is totally different.

*Syrup.*

Only one sample of the fifteen submitted was found to be adulterated, but that contained 50 per cent. of glucose.

*Lard.*

Adulteration, 28 per cent. The adulterants found were cotton-seed oil and tallow.

*Tea.*

None was found to contain other than genuine tea leaves, and but one sample contained too much mineral matter indicating spent leaves. The rigid examination of teas at various ports of entry by government inspectors regularly appointed for that purpose has resulted in practically shutting out spurious teas from our market.

*Vinegar.*

Adulteration, 34 per cent. Any failure to conform to the legal standard of 4.5 per cent. of acetic acid and 2 per cent. of apple solids constitutes adulteration. Samples may contain too little acetic acid

either from insufficient fermentation of the cider or from dilution with water. An insufficiency of apple solids indicates watering, and the substitution of other solids indicates that the vinegar is made at least in part by the fermentation of materials other than cider, — notably molasses. The greater number of adulterated samples fell but slightly below the standard.

### *Olive Oil.*

Adulteration, 26 per cent. The adulterant found was cotton-seed oil. Many of the cotton-seed oil substitutes for olive are now labeled "sweet oil" or "salad oil," terms of such an indefinite significance that technically there is no deception.

### *Miscellaneous.*

Of 116 samples of a miscellaneous description 24 were found not of good quality. Of this number were samples of *pickles* containing notable quantities of alum; *dried apples* containing considerable traces of zinc; *catsup* containing salicylic acid; *fruit syrups* containing salicylic acid, in some instances to the extent of 0.47 per cent.; *salt fish* preserved with boracic acid.

Among the novelties of this class was a sample of "kustard" which proved to be a mixture of corn starch and salt flavored with coumarin.

### *Summary of Food Statistics.*

|                    | Genuine. | Adulterated. | Total. |                  | Genuine. | Adulterated. | Total. |

## DRUGS.

Of this class, 327 samples were examined. Ninety-nine proved to be not of Pharmacopœal quality.

*Acidum Benzoicum*: 3 standard.

*Acidum Hydrobromicum*: 2 standard.

*Acidum Tannicum*: 15 standard; 1 inferior, containing a resin insoluble in water.

*Æther*: 6 standard; 2 inferior, containing too much alcohol.

*Æther fortior*: 3 standard.

*Alcohol*: 15 standard.

*Aqua Ammoniæ*: 5 standard; 2 inferior, containing too much water.

*Aqua Ammoniæ fortior*: 5 standard.

*Aqua Destillata*: 1 standard.

*Bismuthi Subnitras*: 2 standard.

*Cerii Oxulas*: 2 standard.

*Chloroform*: 3 standard.

*Extractum Glycyrrhizæ*: 1 standard; 2 inferior, containing considerable amounts of corn and wheat starch.

*Extractum Malti*: 1 of good quality.

*Ferri et Quinina Citras*: 7 not of the Pharmacopœal standard.

*Glycerinum*: 16 standard; 3 inferior, containing oils reducing nitrate of silver, one sample containing petroleum.

*Iodoform*: 1 standard.

*Lycopodium*: 2 standard.

*Liquor Magnesii Citratis*: 2 standard.

*Magnesii sulphas*: 1 standard.

*Oleum Olivæ*: 9 of good quality; 2 cotton-seed oils.

*Opii Pulvis*: 10 standard, 2 inferior, containing too little mor-  
ie.

*Potassii Acetas*: 5 standard; 3 inferior, containing considerable carbonate and chloride.

*Potassii Citras*: 6 standard.

*Potassii Iodidum*: 6 standard; 1 inferior, containing a considerable amount of chloride.

*Potassii Permanganas*: 6 standard.

*Pulvis Effervescens Compositus*: 13 standard in quality, but of considerable variety of weight, and the blue and white papers transposed in two instances.

*Pulvis Glycyrrhizæ Compositus*: 1 of inferior quality.

*Pulvis Rhei*: 9 standard.

*Quininæ Bisulphas*: 1 standard.

*Quininæ Sulphas*: 7 standard.

*Spiritus Frumenti*: 2 standard; 1 inferior, containing too much solid matter, chiefly sugar. The percentage of alcohol varied from 41 to 53.

*Spiritus Juniperi*: 2 of good quality and 2 inferior, being largely diluted with water.

*Spiritus Limonis*: 1 standard.

*Spiritus Vini Gallici*: 2 standard.

*Sulphur Lotum*: 12 standard; 1 inferior, containing 50 per cent. of gypsum.

*Syrupus*: 1 standard; 1 inferior, containing too much water.

*Tinctura Aconiti*: 6 standard.

*Tinctura Iodi*: 3 standard; 10 inferior, containing too little iodine, the deficiency being from 5 to 30 per cent.

*Tinctura Nucis Vomicae*: 4 standard; 5 inferior. This tincture should contain 2 per cent. of the dry extract. The samples submitted contained from 2.19 per cent. to 0.6 per cent.

*Tinctura Opii*: 25 standard; 27 inferior. This tincture should contain 1.3 to 1.5 per cent. of morphine by the Pharmacopœal assay. The samples submitted contained from 2.19 per cent. to 0.66 per

cent., the strongest tincture being more than three times as strong as the weakest.

*Vinum Album*: 4 samples not of Pharmacopœal quality, containing too much solid residue, chiefly sugar. The alcohol also was found to be from 1 to 3 per cent. in excess.

*Vinum Rubrum*: 16 samples not of Pharmacopœal quality. Here again there proved to be a large excess of sugar, while the alcohol varied from 2 per cent. below to 3 per cent. above the standard.

*Zingiber*: 1 standard.

*Miscellaneous*: 12 of good quality; 1 not of good quality. In this class were included samples of non-poisonous insect fluids composed of benzine, alcohol, peppermint, pennyroyal and borax.

A "wild cherry beverage" contained no hydrocyanic acid.

A sample of patent obesity pills contained nothing to be detected but sugar.

A sample of "freckle lotion" contained forty grains of corrosive sublimate per bottle.

Other face washes selling at one or two dollars per bottle were found to contain alcohol and citric acid in solution, and sulphur, chalk and gypsum in suspension.

A sample of "Black Pepsin" was found to consist of ground annatto and salt. It gave a slight pepsin digestion reaction.

A sample of "Compound Extract of Salix," prepared for preserving eggs, fruit and vegetables, proved to be salicylic acid.

#### SUMMARY.

## PROFESSOR GOESSMANN'S REPORT.

---

The following report comprises the results of the analyses of samples of milk obtained in the four western counties of Massachusetts during the year ending Sept. 30, 1893.

The whole number examined was 187, of which 38, or 20.3 per cent., were below the standard. This result was but slightly greater than that of 1892 for the same district, which was 19.8 per cent.

The results of analyses were as follows : —

|                            |           |      |
|----------------------------|-----------|------|
| Whole number examined,     | . . . . . | 187  |
| Number above standard, .   | . . . . . | 149  |
| Number below standard, .   | . . . . . | 38   |
| Percentage below standard, | . . . . . | 20.3 |
| Samples of skimmed milk,   | . . . . . | 7    |

The statistics of the cities are as follows : —

### CHICOPEE.

## ISOLATION HOSPITALS FOR INFECTIOUS DISEASES.

---

---

# ISOLATION HOSPITALS FOR INFECTIOUS DISEASES.

---

By S. W. ABBOTT, M.D., Secretary of the Board.

---

An increased demand, during the past two years, from the authorities of cities and large towns, and especially from manufacturing towns, for information on the subject of infectious disease hospitals has formed the incentive to the compilation of the following paper.

The essential difference between hospitals established for receiving patients attacked with infectious disease and other hospitals consists in the fact that the latter, the general hospitals, are maintained mainly for the purpose of affording care and treatment for the individual, while the former, the infectious disease hospitals, in affording this care and treatment also provide for the protection of the community at large, and thus constitute one of the essential measures for preventing the spread of infectious diseases by furnishing the means for isolating the first cases which appear in any community.

The principal reasons for providing these establishments in large cities are the following : —

*First.* Isolation constitutes the first and essential principle in the preventive treatment of the majority of infectious diseases. The more perfect the barrier between the sick and the well the greater becomes the certainty of staying the spread of infectious disease. On the other hand, the increasing accumulation of our population in the cities has a tendency to favor the spread of such disease. The urban population of Massachusetts (*i. e.*, people living in cities having more than 8,000 inhabitants in each), was only 27.1 per cent. of the total population of the State in 1840. In 1880 it had increased to 58.4 per cent., and in 1890 to 69.9 per cent. The urban population of the United States had also increased from 22.6 per cent. in 1880 to 29.1 per cent. in 1890.

To illustrate the effect which this crowding together of the population has upon the mortality from infectious diseases the following data are presented. They are the result of observations upon this subject extending over a period of twenty years in Massachusetts.

and were published in the twenty-third annual report of the State Board of Health, page 783, etc. They are here more conveniently grouped together in one table.

*Mortality from Eight Principal Infectious and Destructive Diseases in Dense, Medium and Sparsely Settled Districts in Massachusetts, that of Dense Districts being taken as 1,000.*

|               | MORTALITY FROM |          |                |                       |            |                   |              |            |                |
|---------------|----------------|----------|----------------|-----------------------|------------|-------------------|--------------|------------|----------------|
|               | All Causes.    | Measles. | Scarlet Fever. | Diphtheria and Croup. | Small-pox. | Cholera Infantum. | Consumption. | Pneumonia. | Typhoid Fever. |
| Dense, . . .  | 1,000          | 1,000    | 1,000          | 1,000                 | 1,000      | 1,000             | 1,000        | 1,000      | 1,000          |
| Medium, . . . | 826            | 617      | 818            | 780                   | 332        | 898               | 810          | 792        | 1,100          |
| Sparse, . . . | 760            | 445      | 587            | 634                   | 149        | 639               | 727          | 783        | 1,175          |

In using these terms, *dense* refers to those districts in which there was less than one acre to each inhabitant; *medium*, to those districts in which there was more than one acre but less than four acres to each inhabitant; and *sparse*, to those districts in which there were more than four acres to each inhabitant. By this table it appears that overcrowding has an unfavorable effect upon the mortality of each one of the foregoing diseases except typhoid fever.

*Secondly.* The inability of the majority of laborers and mechanics to furnish separate accommodations for the isolation of members of their families who may become ill with infectious disease is well known. Such families usually live in tenements having from one to four rooms, none of which can safely be devoted to the treatment and isolation of infectious diseases of a dangerous character. The serious overcrowding which prevails in some of the large cities of Great Britain has not yet been reached in any of our large cities, but the tendency is in that direction (Glasgow has a population of more than 100,000 living in one-room tenements). The very great increase of the population of this class by immigration has been the chief factor in causing overcrowding in our cities during the past decade.

*Third.* Another important advantage secured by the isolating hospital is found in the fact that the ordinary duties of the household, the attendance at school, and especially the support of the family by its wage-earners, can be carried on without disturbance, the danger of infection having been removed by the transfer of the sick member of the family to the hospital. It has not unfrequently happened that the local sanitary authorities in some of our cities and

towns have not only rigorously enforced the law relating to non-attendance at school, but have also quarantined the whole family, old and young; so that, by this means, the scholar is deprived of from two to ten weeks, or even more, of his educational privileges at the most important or most receptive period of his life, the length of time depending upon the duration of illness in the infected household; and more than this, the father and other wage-earners have been kept from work in the mill, the factory or the workshop. Even if he is allowed to work, his fellow workmen are wont to regard him with suspicion so long as a case of any one of the infectious fevers exists in his household. Now, the prompt removal of such cases permits the school attendance and the employment of other members of the family to go on undisturbed.

In all my experience with local boards of health during the past few years, I know of no circumstance or condition which has given more serious trouble and perplexity than this, nor do I know of any which is likely to be relieved to so great an extent as is this condition by the introduction of the isolating hospital.

So far as one disease (small-pox) is concerned, the principle of isolation in a hospital specially provided or designed for such purpose has been recognized from a very early period of our history. In 1701 an act was passed by the General Court "for the better preventing the spread of infection," wherein it was provided that "when persons were visited with the plague, small-pox or pestilential or malignant fever, and other contagious sickness, the infection whereof may be communicated to others," the selectmen were empowered to remove such infected persons to separate houses, and to provide "nurses, tendance and other assistance and necessaries for them, at the charge of the parties themselves, their parents or masters (if able), or otherwise at the charge of the town or place where they belong."

Small-pox has been shorn of much of its terrors by the discovery and practice of vaccination, so that while in the last century it furnished a very large percentage of the deaths the ratio of such mortality in the present century has been very greatly diminished.

The number of deaths from small-pox in the twenty years (1871-1890) in Massachusetts was 2,298, while those from measles, scarlet fever, diphtheria, croup and typhoid fever were, respectively, 3,984, 14,639, 36,553 and 19,421. If the ratio of cases to deaths maintained the average which has usually been observed, the total number of cases of these diseases which occurred in the State during

these twenty years must have been at least 700,000. Had adequate provision been furnished for controlling epidemics at their outset, it is safe to say that a very considerable portion of these lives, and also of these cases of illness, might have been saved. The provision of isolating hospitals constitutes one important measure for controlling such epidemics, while prompt notification by the attending physicians, disinfection, vaccination and restriction of school attendance from infected families also constitute a part of the same general plan of action.

Hospitals for infectious diseases have reached their highest type of development in England, but are not yet in very common use in the continental countries of Europe. In commenting upon the history of this subject, Dr. Buchanan says, in his introduction to the special report to the Local Government Board of England upon the "Use and Influence of Hospitals for Infectious Diseases":—

The original design of these hospitals in England was to promote the recovery of the individual poor patient for whom other accommodation was wanting; indeed, the name "house of recovery" was a frequent synonym for infectious disease hospital at the period when such an institution was first seen to be necessary. But it was inevitable that the advantages to be obtained by the district possessing a hospital should soon force themselves upon the attention of the observer, and from a very early period of their history infectious disease hospitals have been advocated on the ground of their protecting the household against the spread of infection.

The benefits of these hospitals were not, however, obtained without a good deal of misfortune within the walls of the institutions themselves. In the small-pox hospital, indeed, this was not apparent. Small-pox had been regarded from the beginning as requiring a special building for itself. It had a "specific" contagion, which could not be safely treated under the same roof with the "general" contagion of fever. So, in the hospital where no disease but small-pox was received, patients had no opportunity of contracting other diseases. The nurses, in early times selected from among those who had passed through an attack of small-pox, and in later times, having their vaccination specially cared for, took nothing from their patients; but in the "fever hospital" the case was different. Doctors and nurses caught fever, in some years more than in others, while convalescent patients had what appeared to be repetitions of fever attacks. So serious indeed did these misadventures become that forty years ago it had come to be spoken of as doubtful whether fever cases, if they were to be treated in hospitals at all, had not better be distributed through the wards of general hospitals. The experiment was tried, but with far greater disaster to the patients and attendants of the general hospital.

In the foregoing quotation the special form of fever to which reference is made is undoubtedly typhus, and not typhoid or enteric fever.

With reference to the propriety of separating isolating hospitals absolutely from all other establishments, Dr. Rowe says in his recent paper upon this subject: —

In large communities the only system that is beyond criticism is to make for infectious diseases a separate establishment, independent and isolated. . . . It is the duty of hospital workers and sanitarians not to cease forcing upon public authorities the necessity of intelligent action, until every municipality, through its public treasury, shall provide special hospitals always available for infectious diseases. Is it not the wisest policy to put such hospitals under the immediate control of the local board of health? They have so close a connection with other vital matters properly belonging to health boards that it conduces to unity of action to have the suppression of infection under one authority, a practice that obtains in Great Britain.\*

As early as 1866 an act of Parliament had given to local authorities the power to erect and to maintain hospitals for isolation of persons suffering with contagious diseases. This power was further enlarged by the general Public Health Act of 1875. As a result of this legislation it was found by returns made in 1879 that 296 authorities had availed themselves of this privilege in the erection of buildings of one sort or another for this specific purpose. The arrangements were in some cases rudimentary and insufficient, and on the other hand some authorities had wisely and liberally used their powers in providing efficient hospitals for the reception of persons suffering with contagious fevers and from small-pox.

In a brief paper upon the same subject presented at the International Congress of Hygiene at London in 1891, Dr. Thorne states that this number had increased to 400, and that the general adoption of the provisions of the Infectious Disease (Notification) Act of 1889 was likely to lead to a still further increase in the number of these establishments.

In commenting upon the diseases calling for isolation, Dr. Thorne says: —

So far, there is no evidence that aggregation of the infectious sick suffering from any of these diseases, except small-pox, such as is likely to be carried out by any ordinary sanitary authority, leads to infection of the

---

\* Paper read at Congress of Charities, Correction and Philanthropy, at Chicago, June, 1893.

surrounding community, provided that the hospital be properly constructed and administered, and subject to a zone of some forty feet being provided between all buildings intended to receive infected persons or things and the boundary wall, or close fence around the site. Experience has shown that it is otherwise with small-pox, and it yet remains to be ascertained what are the circumstances under which cases of that disease can be aggregated for the purposes of sanitary authorities without risk to the community. Fortunately, owing to the protection afforded by vaccination, small-pox does not, as is commonly supposed, stand foremost among the infectious fevers calling for isolation in a hospital. As a rule, port sanitary authorities alone make provision for cholera.

*Extent of Provision.* — No exact rule can be laid down as to the requisite amount of provision for any given population. A general estimate has been made in England of one bed to each 1,000 inhabitants as sufficient for ordinary requirements. But the character of the population must largely determine this question. Upon this point Dr. Thorne says: —

In a locality where the population is well-to-do, and most houses are of a size and construction that offer reasonable facilities for the isolation of single attacks of the current infectious fevers, the amount of hospital accommodation needed for public health purposes will be less than in a manufacturing district, where disease cannot be treated in the houses in which it breaks out without very great if not certain risk of spread.

With this point in view, it is quite plain that the amount of hospital provision per 1,000 inhabitants in a residential community like those of Brookline or Newton would necessarily be less than it would be in manufacturing cities like Lowell, Lawrence, Fall River and Worcester.

*Character of Accommodation Required.* — Dr. Thorne has so distinctly presented the essential conditions relative to the necessary accommodations of an infectious disease hospital in his recent paper at the International Congress of Hygiene, that I take the liberty to quote them as applicable in most particulars to our own cities: —

Premising that all the conditions that are deemed essential in the provision of a healthy dwelling-house are to be regarded as equally desirable in the case of an infectious hospital, I would only here refer to such other points as involve considerations peculiar to such hospitals.

(a) *As regards site.* — It is, as a rule, undesirable to select any site which is less than some two acres in extent; and, even then, regard should

be had to the need for extension of hospital buildings, whether for temporary purposes or owing to increase of population. Where practicable, only single-story hospital pavilions should be contemplated; and having regard to their distribution on the site, and to the outdoor exercise of convalescents, twenty patients to the acre will generally be found to be the limit of aggregation of sick on area.

(b) *As regards buildings.* — The administrative building should be distinct from all others. Nurses, when off duty, will live and sleep in it; tradesmen will call there for orders and with supplies, and relatives will there make inquiries as to the progress of the sick. This building should always be so placed as to control all access from without to the ward pavilions and other hospital buildings. The laundry, ambulance shed, disinfecting apparatus and mortuary should also be in one or more buildings separate from the administrative building and the ward pavilions.

No sanitary district can be regarded as properly provided for unless it has immediately available sufficient accommodation for the isolation of two different infectious diseases in both sexes, and some means for the special isolation of one or two patients needing separate accommodation, as, for example, cases in which the nature of the disease is at first doubtful. These requirements are usually met by the provision of two pairs of wards or rooms having no aerial communication with each other, together with one or two special isolation rooms. In sparsely populated districts these requirements may be combined in one pavilion, the separate apartments of which open separately upon verandahs. Such a building is commonly styled an isolated pavilion.

Each ward pavilion should admit of cross ventilation by means of windows in the two opposite side walls; the closets and ward sinks, having themselves independent means of cross ventilation, should be entered from the wards by means of a cross-ventilated lobby; all angles, vertical and horizontal, should be rounded, to prevent deposit of dust, etc., and a nurse's duty room should be provided. Assuming that each ward will contain the ordinary proportion of acute and convalescent patients, and that it is adequately ventilated and warmed, a minimum of 2,000 cubic feet of air per head is generally found to suffice in order to maintain reasonable purity of air; but much depends on the allotment of this amount of air to the individual patient. No excess in the amount of total air provided — as, for example, in the case of lofty wards — can compensate for crowding patients on the floor level; and hence the beds should be so arranged as to ensure for each patient a floor-space of some 156 square feet. And since it is in the neighborhood of the patient's mouth and nostrils that it is above all important to maintain the purity of ward air, it is of all things necessary to allot to each bed a separate amount of wall space, not less than some twelve feet in length.

(c) *As to allotment of bed-space.* — The best position for the beds is that one bed should occupy each one wall-space between a pair of win-

dows, the head of the bed to be at least one foot away from the wall, so as to facilitate movement of air about the patient's head.

Medical advice is often sought as to the number of beds that should be placed in any one ward of an infectious hospital. In suggesting an answer to this question I cannot avoid the conclusion that the practice of treating sick persons under circumstances which admit of the air by which they are surrounded being charged more or less by the emanations of other sick persons is wrong in principle, and that from this point of view any aggregation of the sick in wards is undesirable. But other considerations must, in the case of a large proportion of the population, be regarded as outweighing this one; and all that can be properly contended for is that the limit of such aggregation shall be decided by considerations such as are involved in securing freedom from any recognizable risk, together with such efficiency in general administration and nursing as is consistent with a reasonable regard for economy.

The several infectious fevers doubtless differ in regard to the amount of nursing which the sick require; but taking them as a group, and assuming that the ordinary proportion of acute and convalescing cases at varying ages are brought together, it may be held that any one nurse can rarely be expected to take charge of more than twelve patients. The moment this number is exceeded the nursing staff has to be doubled, and directly a second nurse is required it would be better in the interests of the sick that those whom she nurses should be in a separate ward. Holding this in view, I believe it will generally be found desirable that infectious hospitals should be built in pavilions so contrived that in each there shall be two wards, one for males and the other for females, containing together not more than twelve beds, the two six-bedded wards to be separated by nurses' duty-room and an entrance lobby.

*The diseases for which persons may properly be treated in infectious disease hospitals* are mainly those which are specially contagious in their nature, and are liable to spread from the sick to the well in consequence of proximity to each other in the small and ill-ventilated tenements of large cities. It frequently happens also that travellers stopping at hotels or boarding-houses are attacked with some infectious disease, and the business of the establishment is seriously hindered and sometimes stopped altogether for a time by the presence even of a single case of such disease. I have had occasion several times in the past ten years to investigate instances in which these circumstances were prominent. Under ordinary rules such cases cannot be admitted to the general hospital, but may very properly be taken to an isolation hospital for treatment.

The diseases which should be treated in infectious disease hospitals are scarlet fever, diphtheria, small-pox, measles, typhus fever, cholera, typhoid fever, and to these it would be proper to add in the Southern States yellow fever, a disease from which the New England States are generally exempt.

Practically, the first five diseases mentioned in the foregoing list are those for which provision is usually made in isolation hospitals. In referring to English practice upon this point Dr. Thorne says :—

Next to small-pox, scarlet fever is the disease for the isolation of which most efforts have been made by sanitary authorities. The various forms of continued fever, and notably cases of enteric fever, have also in many districts been somewhat extensively isolated. Diphtheria and erysipelas have occasionally been dealt with in isolation hospitals, and at times efforts have been made to stay the spread of measles in the same way. There are, however, conditions which render attempts to deal with measles by means of isolation specially difficult. The stage at which the disease becomes infectious often precedes that in which it is recognized; the subjects of its attack are as a rule of exceptionally tender years, and a large proportion of cases never come under medical treatment at all. Notwithstanding its fatality, therefore, it can hardly be expected that hospital provision by sanitary authorities will be deemed as pressing in the case of measles as in some other infectious diseases.

Scarlet fever is the disease for which isolation is most constantly and most urgently needed. The mortality it occasions exceeds that of any other communicable fever prevalent in this country. It is highly infectious, and there are no effectual means apart from isolation by which its spread can be stayed. Small-pox, the one disease which, if vaccination were properly carried out, should least call for hospital provision, may perhaps be deemed to stand next in order as regards the measures for isolation. In some towns typhus has prior claims to small-pox in this respect, and in all districts some provision should be made for the other continued fevers.

The foregoing extract from Dr. Thorne's report applies with equal force to the case of our own cities and towns at the present time, with this exception, that we should give much greater prominence to diphtheria as a disease requiring hospital isolation. The very slight importance apparently attached to diphtheria in the English report of 1880 is undoubtedly accounted for by the fact that the contagious character of the disease was not then so thoroughly established as it is at the present time, a dozen years later. A peculiar characteristic of diphtheria appears to be the permanence of its infection, and the liability to retain its vitality in houses and apart-

ments for a considerable period of time. Hence the propriety of speedy removal of infected persons to a special hospital constructed with reference to efficient methods of disinfection, which are ill-adapted for use in old, crowded and ill-ventilated tenements, which, with walls and floors and ceilings having many cracks, crevices and crannies, give abundant opportunity to harbor the specific infectious material of diphtheria.

While the mode of transmission of the infection of typhoid fever differs essentially from that of some of the other infectious diseases already named, it is undoubtedly true that many cases occur by means of personal infection from one person to another, and while the alimentary tract is the part through which the specific poison is received, and often by means of the public or private water supply, the fact should not be overlooked that there may be other modes of transmission than through the medium of the water supply. While writing this paper I had occasion to investigate a local epidemic in a small town, having circumstances which may briefly be stated as follows: In January last, a man was attendant as a nurse and watcher upon a typhoid fever patient living about two miles distant from his own house. After the recovery of the patient he went home and was taken ill with typhoid fever himself, and after him, successively, three of his children, a grandchild, and finally his wife, the disease having in his household a continuous history of six months' duration. Careful examination was made of the surroundings of the house, the water supply, the disposal of refuse, etc., and it did not appear that the local conditions were at fault, but the probability lay in the direction of personal infection from the first case to the second, and so on through the family. Doubtless food and possibly milk may have been a means of transmission of infection; but if the first case could have been taken to a hospital and isolated during his illness and convalescence, it is probable that all the remaining members of the family would have escaped the disease.

This is only a single example of multitudes of such cases, which are constantly recurring and in which a system of well planned isolating hospitals would necessarily diminish very greatly the number of cases of illness as well as the mortality. The practical result of such a plan when properly administered, is to limit outbreaks of infectious disease to the first cases and thus to prevent the occurrence of epidemics.

*Further points relative to construction.*—Brick, stone or iron are undoubtedly better than wood, and this statement applies more decidedly to infectious disease hospitals than to those which are to be used for general purposes. Especially is this true of the interior finish of wards and other apartments used by the sick. It is advisable to finish the walls and ceilings with a hard or impermeable surface, which has no cracks or inaccessible ledges which may retain infection, and a floor of best asphalt or of some similar impermeable material, although possessing slight disadvantages, is so much superior to wood for the purpose of cleaning, as to be well worthy of adoption for such uses in wards which are to be devoted to the most infectious diseases.

In adapting dwelling houses in small districts to the uses of infectious disease hospitals special care should be taken to select houses in isolated positions. Such buildings should not be used for this purpose in large cities.

Such hospitals should be erected in a careful and considerate manner, with due regard to growth of population, and upon a well defined plan. Dr. Thorne's inquiry showed that—

The suitability of the hospital buildings in various parts of the country was to a very great extent dependent upon the circumstances under which they were erected. If a hospital is hurriedly built under the influence of panic, it is often not ready for occupation until the immediate cause of its erection has passed by; it provides accommodation of a very indifferent sort; it fails, almost without exception, to meet the permanent requirements of the district even when in amount it turns out to be more than the district needs; and thus the object of the hospital as a part of the sanitary defences of the district is often attained in a very imperfect manner and at a needlessly large cost.

*Possibility of spreading infection.*—It has sometimes been urged that such hospitals might become centres of infection from which diseases would spread to the neighboring districts. Careful investigation upon this point, however, among the numerous hospitals of this sort in Great Britain showed that no danger need be feared from this source except in the case of small-pox. A thorough investigation made by Dr. Power, in 1882, and reported to the Local Government Board, showed that in the neighborhood of the Fulham small-pox hospital in London, small-pox had increased almost in a direct ratio to the nearness of the population to the hospital. This

increase was also independent of lines of human intercourse. In point of time there was also a very marked relation between the varying use of the hospital and the manifestations of excessive small-pox in the neighborhood.

Hence much greater care is necessary in selecting an isolated site in the case of hospitals intended for the reception of small-pox patients than is necessary in the case of those which are to be used for other infectious diseases.

The following condensed table and general conclusions are taken from Dr. Power's report :—

*Admissions of Acute Small-pox to Fulham Hospital, and Incidence of Small-pox upon Houses in Several Divisions of the Special Area during Five Epidemic Periods.*

| CASES OF<br>ACUTE SMALL-<br>POX ADMITTED. | In Epidemic Periods<br>Since Opening of<br>Hospital. | INCIDENCE ON EVERY HUNDRED HOUSES WITHIN THE SPECIAL<br>AREA AND ITS DIVISIONS. |                                              |                                                         |                                                          |                                            |

#### CONCLUSIONS RELATIVE TO THE SPREAD OF SMALL-POX IN THE NEIGHBORHOOD OF HOSPITALS.

1. There has been in each epidemic period an excessive incidence of small-pox in houses in the neighborhood of the hospital as compared with more distant houses in Chelsea, Fulham and Kensington.

2. The percentage of houses invaded in the neighborhood of the hospital has become gradually smaller as the distance of the houses from the hospital has increased.

This gradation has been very exact and very constant.

3. Houses upon the chief lines of human intercourse with the hospital have not suffered more than houses lying in other directions from the hospital.

4. In point of time, there has been a very marked relation between the varying use of the hospital and the manifestations of excessive small-pox in the neighborhood.

This relation has not shown itself while the use of the hospital has been for convalescents only.

5. The appearance of excessive small-pox in houses around the hospital has never been delayed until the hospital has become full, or nearly full. It has been always most remarkable at the time when admissions to the hospital were beginning to increase rapidly.

In the succeeding months of active operations, though the use of the hospital may have gone on increasing, the excess of small-pox upon the neighborhood has habitually become less marked.

6. On comparison of different epidemics an almost constant ratio is observed between the amount of the hospital operations and the degree of excess of small-pox in the neighborhood.

7. The machinery of the hospital administration, with inclusion of defects in that machinery, does not account for the peculiarity of small-pox incidence within the three parishes of Chelsea, Fulham and Kensington since the establishment of the hospital.

8. There must have been some condition or conditions operating to produce the observed distribution of small-pox around the hospital that have pertained to the hospital as such, and that have been in excess of the condition of small-pox extension as usually recognized.

9. During the present epidemic period, and most probably during former similar periods, there has arisen in the atmospheric circumstances of the time, peculiar facility for the dissemination in an undamaged state of any matter that may have been given off from the hospital.

*Disinfecting Apparatus.* — An isolating hospital can hardly be said to be complete in all its appliances without a well-equipped disinfecting apparatus. This may be used, not only for the purpose of disinfecting the infected material which must necessarily be found in every such hospital, but will also prove a powerful ally to the local board of health for the disinfection of the infected articles which are to be found wherever scarlet fever, diphtheria, typhoid fever and other infectious diseases exist. Such articles include clothing, bed linen, mattresses, and all the textile fabrics which are capable of disinfection and are too valuable to be destroyed. Such disinfecting stations exist in Berlin and in Paris as separate establishments, and are conducted in the most thorough manner, and in accordance with the most approved methods. There is no reason, however, why they may not be employed as adjuncts to isolating hospitals, where such hospitals exist. The Board of Health of Boston has during the past year established such a station at its new infectious hospital at Swett Street.

Efficient forms of disinfecting apparatus are also made for use in a portable shape, and are now made, both in this country and in Europe, at considerably less cost than the stationary establishments.

---

Let us for a moment consider a practical illustration of such a system as I have outlined: A father, mother and four small children, the latter aged two, four, six and nine years, occupy a tenement of two rooms, including a kitchen and sleeping room, each about twelve feet square and seven and a half or eight feet high. The kitchen is the cooking and living room of the family, and both are heated by the kitchen stove. The sleeping room is occupied at night by the whole family, and after allowing for the space taken by the furniture there are in this room about 175 cubic feet of air space only to each person, which is doubled by the open door into the kitchen. The sleeping room has but one window, which, in winter, is kept constantly closed, and there is no special means for ventilation. I am not here describing an unusual case, but, on the contrary, one which is of very common occurrence in any one of our large manufacturing cities.

One of these little children is taken ill with diphtheria in its severest form. There is no provision in the city for such cases, and the mother gives the child the best care which she can afford under the circumstances. The neighbors are afraid to take the other children to their homes. The next child is too young to attend school, and the law excludes the older children from school during the prevalence of illness in the family, thus making their exposure to infection more certain. After days of weary watching another child falls ill, and then perhaps the mother herself, worn with care and solicitude for her little ones, becomes a victim to the disease. Meanwhile the youngest has died, and is laid out for burial in a corner of the kitchen, the living room of the family.

Dr. Russell, the health officer of Glasgow, in commenting upon such cases, which, in a crowded city like Glasgow, were once of very frequent occurrence, says, when contrasting the condition of the rich and of the poor: —

Last of all, when *you* die, *you* still have one room to yourself, where in decency you may be washed and dressed and laid out for burial. If *that one room* were your house, what a ghastly intrusion you would be. The

bed on which you lie is wanted for the accommodation of the living. The table at which your children ought to sit must bear your coffin, and they must keep your unwelcome company. Day and night you lie there until with difficulty those who carry you out thread their tortuous way along the dark lobby and down the narrow stair through a crowd of women and children. You are driven along the busy and unsympathetic streets, lumbering beneath the vehicle which conveys your scanty company to the distant and cheerless cemetery, where the acrid and deadly air of the city in which you lived will still blow over you and prevent even a blade of grass from growing over your grave.

Dr. Russell has here graphically described a death among the abodes of the poor, but when the death is from infectious disease, the conditions are still worse, since the added danger of infection to the remaining members of the family only doubles the distress of the household. Now for such conditions as I have described the infectious disease hospital provides a most excellent remedy, and while it may not prevent the occurrence of the first case in the family, it does provide for the taking of the infected person to a suitable place where he will not only receive far better care himself, but will not transmit the infection to his brothers, his sisters or to any other person.

In the hospital, too, in place of overcrowded and ill-ventilated bed chambers, there are large and well-ventilated wards; in place of foul air and darkness, there is fresh air and sunlight; in place of scanty food and food that is ill adapted to the wants of the sick there is food selected especially for the case in hand, and more than all this, there is good nursing and the best of care, and when the patient has recovered he is returned to his family, no longer a source of danger and of infection.

Of the few establishments of this character now in use in this State, one is at the State Primary School at Monson, where it was built about ten years ago for the purpose of receiving any cases of infectious disease which might arise in the school. It has proved exceedingly useful for the purpose of isolating such cases of scarlet fever, diphtheria and measles as have occurred in the school, and has undoubtedly prevented the outbreak and continuance of severe epidemics of these diseases, which are very liable to occur among children of such ages as are usually received at this school. When no means are provided for isolating sick children such epidemics often make sad havoc among them.

This hospital contains four wards capable of accommodating about twenty to thirty patients. It is entirely separated from the other buildings.

PLAN OF HOSPITAL FOR INFECTIOUS DISEASES AT CAMBRIDGE.

Still more recently an isolating hospital, very well planned and conveniently arranged, has been built at Cambridge, under the supervision of the trustees of the Cambridge Hospital.

A general plan of the main floor of this building is shown upon page 706. The arrangement of wards in this building is so planned as to admit of the treatment of two diseases, and also of the two sexes in each case, without any possible communication between the two halves of the hospital. Fourteen beds can conveniently be accommodated in the building. There are also two rooms for nurses in a second story not shown in the plan, separate from each other, each room being reached by a separate stairway.

In describing the conditions essential to a well-contrived isolating hospital for a large city, Dr. Rowe makes the following valuable suggestions, some of which could hardly be carried out to the letter, except in large and wealthy communities :—

The wards should be of moderate size, not to exceed thirty beds. The number of buildings for each disease should be sufficient to allow one building to, so to speak, "lie fallow" for renovation and disinfection. This reserve is a large factor in reducing the mortality in an infectious disease hospital. This generous installation of site, buildings and appointments is not always practicable, either from the topography of a city, an available site or the financial condition of a municipality. Such establishments, however, do exist. The Belvidere Hospital for Infectious Diseases in Glasgow, Scotland, is a most notable example. It covers thirty-one acres of land, and has thirty-five buildings with accommodations for infection usually prevalent in a large city. No better argument for isolation hospitals can be adduced than a rehearsal of the experience of the health authorities of Glasgow, in changing the most unhealthy city of Great Britain, with the largest mortality rate, into a clean, healthful city, with a low death-rate.

Acting in conformity with the principles which Dr. Rowe has laid down in the paper from which I have here quoted, the trustees of the Boston City Hospital have now made provision for this purpose upon a lot of land near the city hospital in Boston. The group of seven buildings comprising this hospital, now nearly completed, consists of two two-story ward pavilions, connected by covered corridors with an administration building. The other buildings are a convenient lodge-house, a nurses' home, and a boiler-house, laundry, mortuary, etc. The cut on page 708 shows the first floor of one of the two ward-pavilions now approaching completion. As at present arranged, the wards are designed for 136 patients.

The wards at the City Hospital, now occupied for the reception of patients ill with diphtheria and scarlet-fever, were intended for only forty-two patients, but the urgent demands made upon the hospital

CONTAGIOUS DISEASES.**

SCALE

for receiving this class of cases has required them to be occupied by sixty patients much of the time.

“These difficulties,” say the trustees in their report of the year 1892, “will soon be remedied by the completion of the Chester Park Hospital. For the purpose of carrying out this work \$271,000 were placed at the disposal of the trustees for the construction of new buildings, \$24,000 were set apart for the construction of a new ambulance stable, and contracts were made for the buildings, to cost \$203,000.”

In referring to this department of the work of the city hospital for the year 1892, Dr. Rowe says :—

The contagious service has been extremely active, a larger number of patients having been admitted than during any previous year. The total number of patients admitted with scarlet fever, diphtheria and other complications was 788. . . .

The diphtheria ward has seldom been crowded, although during several months it has been full. The character of the cases was severe, the marked characteristic being that a very large number were brought to the hospital in the last extremity. It follows that the mortality has been large. The scarlet fever ward has not only been full at all times, but during the winter months it has been crowded beyond a limit that was judicious. The hospital attempted to provide for all cases of scarlet fever that applied for relief. . . . Some applicants have been rejected because the wards were crowded to an extent detrimental to those under treatment. . . . When the new hospital for contagious diseases is completed it is expected its capacity will meet not only the present demands but also provide for any epidemics such as have hitherto existed in Boston, and also keep pace with the growth of the population.

The increasing favor with which hospital treatment for infectious diseases is regarded by the public is shown by the fact that in London the numbers admitted to the hospitals of the Metropolitan Asylum's Board increased from 2,197 in 1886 to 8,334 in 1890. One-third of all the infectious cases legally admissable were treated in those hospitals in 1890. In Brighton, England, in 1891, 70 per cent. of scarlet fever cases were so isolated.

“The whole drift of hospital provision is toward the prevention of epidemics by the isolation of first cases of infectious disease, the improvement of the treatment of the cases admitted upon that obtained at home being but part of the main object, but tending materially to diminish the mortality.”

A very good illustration of a small and well-designed isolation hospital for a residential town of 20,000 inhabitants, or for a manu-

facturing town of a smaller population, may be found in the hospital at Ealing, England, which is represented in the accompanying illustrations. The grounds cover about two acres in a convenient location upon the outskirts of the village. The plan includes a hospital for about twelve or sixteen beds, with wards for two diseases, and opportunity to separate the sexes.

An administration house, porters' lodge, laundry, mortuary, ambulance shed and disinfecting apparatus are also provided. The grounds are surrounded by a brick wall about six feet in height. Space is also shown where tents may be erected upon a concrete floor in case of an unusual epidemic. The same space may also be used for future hospital extensions.

The cost of this establishment was about \$30,000, including cost of land.

In the construction of buildings of this character the same general rules should be adopted as are applicable to hospitals in general. The trustees or committees appointed to take charge of construction should make themselves acquainted with everything requisite to secure the best buildings for hospital purposes which modern science and trained experience can produce. In illustration of the neglect of this precautionary measure Mr. H. C. Burdett, author of "*Hospitals and Asylums of the World*," cites the following instance : —

This very autumn we had to inspect a new hospital, costing many thousands of pounds, where the committee and medical staff had taken infinite pains to secure a type of buildings which should be so good as to make their institution an example for others to follow. We found, however, that the buildings actually erected were a failure, and, what is more, a failure of the worst kind ; that is to say, the faults were such as to astonish any one who had taken the trouble to make himself practically acquainted with modern progress in hospital construction. These faults were not due to the character of the site, or to any special circumstance, but arose entirely from ignorance, and what we venture to think is worse than ignorance, namely, an attempt on the part of the architect to adopt what he believed, no doubt, to be modern improvements without making himself acquainted with the purposes those improvements were intended to effect.

One of the first hospitals of this class was the London Fever Hospital, established about 1802, at Gray's Inn Road, and then known as a "house of recovery," where patients convalescing from *infectious diseases* could be taken while their homes were being cleansed or disinfected. It was afterward removed to better quarters, where

it served the purpose of isolating the infected sick, and thus protecting the healthy part of the population. (See plan of present London Fever Hospital, page 713.) The rows of dwellings upon each side of this hospital show its close relation to the neighboring population.

Since the scope of this paper will not admit of the details of hospital construction the reader may be referred with advantage to the excellent work of Mr. H. C. Burdett recently published, entitled “Hospitals and Asylums of the World.”

In the fourth volume of this work are given brief descriptions of the following hospitals devoted to the care of persons suffering with infectious diseases : —

\*London Fever Hospital.

| Small-pox Hospital, Highgate (Lon.).

*Hospitals of the Metropolitan Asylum's Board.*

\*Eastern (Homerton).

| Western (Fulham).

South Western (Stockwell).

| North Eastern (Tottenham).

\*Northern (Winchmore Hill).

| Hospital Ships (Long Reach).

Northwestern (Hampstead).

| \*Ambulance Stations.

\*South Eastern (New Cross).

*Provincial Infectious Hospitals.*

Belvidere Hospital (Glasgow).

| Netherfield Institution for Infectious Diseases (Liverpool).

\*Bradford Fever Hospital.

Bolton Borough Hospital.

| \*New City Hospital (South), Grafton Street (Liverpool).

\*City Hospital for Infectious Diseases (Newcastle-upon-Tyne).

Delancey Hospital (Cheltenham).

| Nottingham Borough Epidemic Hospital.

Gateshead Hospital.

| Port Sanitary Authority's Hospital (London).

\*Heathcote Hospital (Leamington).

Hull Corporation Sanatorium.

| \*River Tyne Port Sanitary Authority's Hospital.

Infectious Hospital for the Joint Counties (Carmarthen).

Isolation Hospital (Huddersfield).

| Sanitary Hospital at Bournemouth.

Isolation Hospital (Oldham).

| Sheffield Borough Hospital for Infectious Diseases.

Isolation Hospital (Hornsey).

| Sittingbourne & Milton Joint Infectious Hospital.

Kendray Fever Hospital (Barnsley).

Ladywell Sanatorium (Salford).

| Temporary Small-pox Hospital (Liverpool).

Leeds House of Recovery.

Monsall Hospital at Manchester.

*Continental Infectious Hospitals.*

\*Blegdams Hospital (Copenhagen).

\*Ullevold's Hospital, Christiania Communal Epidemic Hospital (Sweden).

Oresunds Hospital.

*School Sanatoria.*

Rugby School Sanatorium.

King Edward VI.'s School, New Sanatorium (Sherborne, Dorset).

Blundell's School, New Sanatorium (Tiverton, Devon).

## LONDON FEVER HOSPITAL LIVERPOOL ROAD. LONDON. N.

*Probationary Wards.*

In all infectious disease hospitals of considerable size it is desirable to establish probationary wards for the observation of doubtful cases. It is often very difficult to make a correct diagnosis at the outset of a case of infectious disease. Meanwhile great danger is incurred by the family or the household with whom the patient may be residing. It therefore is a matter of considerable importance to provide a place where the patient may be kept under such surveillance as will avoid danger to others, if the case proves to be infectious, and at the same time may avoid the infection of the patient if it so happens that his illness proves to be either non-infectious or a less dangerous disease.

*School Sanatoria, or Isolating Wards.*

A useful application of the system of infectious disease hospitals is found in its adaptation to the uses of large institutions of learning, or establishments of any sort in which young people are congregated, either for educational or for other purposes, away from their homes.

It is by no means a matter of uncommon occurrence for an outbreak of infectious diseases to take place among the inmates of institutions of this character. Such outbreaks invariably disturb the harmony of the college, school or other institution, and seriously interfere with the regular exercises. Many instances of such outbreaks are not only on record, but in some cases it has happened that the whole school or college population has been broken up and sent to their homes.

The existence of a single building, in which the first cases of infectious disease could be isolated and cared for until convalescence ensued, would in many instances have obviated much of this trouble.

Every large educational establishment should possess an isolating ward or hospital, which could in emergencies be used for this purpose.

While the infectious diseases of childhood are not so fatal nor so frequent among persons of school or college ages, their occurrence is yet sufficiently common among this class to require extreme care for their prevention, as the following figures will show.

The deaths from certain infectious diseases among persons between the ages of fifteen and thirty years in Massachusetts, during

the period of twenty-eight years ending with 1890, were as follows :—

|                            |       |
|----------------------------|-------|
| From measles, . . . . .    | 276   |
| “ scarlet fever, . . . . . | 763   |
| “ diphtheria, . . . . .    | 1,480 |
| “ small-pox, . . . . .     | 1,171 |

To the foregoing figures should be added the deaths from typhoid fever, a disease which finds its victims in the period fifteen to thirty years in the greatest numbers. The deaths from this disease at those ages for the same period in Massachusetts were 11,993.

Phthisis claims a much larger harvest from this age period than either of the foregoing diseases, the number of deaths being 57,197 for the same time and ages. In the case of phthisis, however, while its infectious character must be recognized, the peculiar nature of the disease unfits its victims for the continuance of prolonged study, and all such persons should be advised to discontinue their connection as soon as the nature of the disease is recognized.

Dr. Sykes concisely explains the differences between residential and non-residential schools with reference to the subject of isolation as follows :—

There is a strong contrast in the manner in which personal infection is spread in non-residential and residential schools. In non-residential schools children from various households meet at a centre, become infected, and returning, distribute the infection broadcast, closure being resorted to for the purpose of checking its spread. In residential schools, on the other hand, the infection is more or less confined to the limits of the school, and is only distributed beyond upon the disbandment of the pupils. Hence, it is interesting to note that opposite results may follow the similar process of closing a school, in the two cases, unless extreme precautions are taken.

Residential schools, like other residential institutions, protect themselves from admitting infected scholars from without by requiring certificates of freedom from infection, or from contact with infection, upon admission ; and, when invaded, from the spread of infection within, by isolation in proper quarters. Non-residential schools, where the attendance is daily, do not admit of the application of measures of protection in this form, and are dependent upon school-teachers immediately excluding from attendance children suffering from infectious disease, or being members of an infected family or household. This exclusion can only be enforced by the teacher or manager being informed by the parents or by the sanitary authority of

the cases of infectious disease occurring amongst the scholars. Compulsory notification is therefore a valuable protection to schools. If exclusion fails, and infection reaches a school, not directly but indirectly, by the commingling of infected with healthy children beyond the precincts of the school, it points to the absence of proper seclusion of the infected children at home or in hospital, and it is only when seclusion; as well as exclusion, fail to prevent an epidemic in a school that dissolution or closure of the school is justifiable. Defects of internal condition, structure or site liable to lead to such a result are naturally also included in such justification.

The memorandum\* issued in December, 1890, by the chief medical officer of the Local Government Board explains in a very full and lucid manner the measures necessary to be taken in this direction for the protection of "public elementary schools" by sanitary authorities.

#### SUMMARY.

The advantages of the separate hospital for infectious diseases may be summed up briefly, as follows:—

1. They allow the complete isolation of the sick in cases where the sick cannot be effectively separated at their homes.

2. The work of the wage-earner, the ordinary duties of the household and the school attendance of children can go on as usual without interruption.

3. Infection is thus kept by itself in a place where it can be intelligently treated and destroyed. Otherwise, in tenement-houses and crowded dwellings, and among those who are ignorant of its nature and its proper management and control, it may spread and cause infinite harm.

4. Cities requiring such hospitals should not wait for the hurried impetus derived from panic, but should construct carefully and thoroughly, and with due regard to their own special needs. Such hospitals, like fire departments, when completed should be always ready for immediate use. They should be accessible and under wise and intelligent management.

## APPENDIX.

## PRACTICE OF DIFFERENT COUNTRIES.

In the following pages are grouped some of the essential data relative to the progress of different countries in this particular direction for preventing the spread of infectious diseases.

For a portion of this information the writer is indebted to Dr. Palmberg's recent work entitled "Public Health in its Applications in Different European Countries."

## ENGLAND.

*Memoranda of the Local Government Board of England.**Regulations as to Hospitals (Memorandum on Hospital Accommodation).*

— Means for separating the sick from the healthy should always be provided. When two contagious diseases break out at the same time, they should each be separately isolated.

In towns, and for several villages of smaller size, there should be provided at least two special wards with four beds in each, in order that the sick may be isolated from the commencement. Such a very small infirmary would be very valuable for arresting the progress of an epidemic.

Fig. 1 represents a very simple type of hospital, having one ward for each sex, with the necessary annexa. This plan accompanies the memorandum of the Local Government Board.

Fig. 2 represents two sections of the same building, the one to the left having simple walls and serving for summer rooms; the one to the right having double walls is a permanent structure. At the base of the external walls are openings for the admission of fresh air, seen on the front of the elevation (Fig. 1). In the roof are other openings for the escape of foul air, but chimneys or special tubes are the best for this purpose.

In rural districts without a hospital, a trustworthy married couple without children may be charged with the isolation and care of cases of infectious disease. In the event of a more serious epidemic, several lodgings may be hired for the sick, or they may be isolated in temporarily erected tents or barracks.

Fever hospitals in urban districts ought to have one bed for every 1,000 inhabitants. In manufacturing towns with a very dense population, this proportion ought to be even greater; while in wealthy and less dense towns, with houses of a good class, one bed for every 2,000 inhabitants may suffice.

Permanent fever hospitals are built on the system of separate pavilions. There must be at least four wards for patients, as well as a pavilion for administration.

Sick wards can be arranged in pavilions connected in pairs, as shown in Fig. 3, which is taken from the memorandum of the Local Government

FIG. 1.—PLAN AND ELEVATION OF A SMALL HOSPITAL.

FIG. 2.—VERTICAL SECTIONS THROUGH SAME HOSPITAL.

Board. The dotted lines in this figure show how, as the population increases, the permanent hospital can be enlarged.

The minimum distance between the pavilions should be thirty feet.

Fig. 4 shows another arrangement of sick wards which is preferable when sufficient ground is available.

Fig. 3 - PERMANENT HOSPITAL IN PAVILIONS.,

The sick wards may also be placed on different stories of the same pavilion.

Two of them, one for each sex, are reserved for persons suffering from the same infectious disease.

All the wards should be kept separate, and independently warmed and ventilated. To facilitate the work of the staff a corridor connects all the

Fig. 4 - ANOTHER ARRANGEMENT OF PERMANENT HOSPITALS IN PAVILIONS.

Wards for patients with ten beds in each, lavatory and bathroom (a, b) next the corridor; closets and sinks (c, d) at other end, separated from ward by a cross-ventilated corridor.

pavilions. The latter should be so placed that the air can circulate freely between them. The space between the pavilions should be at least one and a half times as great as the height of each pavilion; and if a pavilion is intended for small-pox, the distance should be still greater. It is preferable to place small-pox in an entirely separate building as remote as possible from all other buildings.

In wards for infectious diseases there should be openings for admission of fresh air between each bed, a little above the floor, so that pure air bathes the patient's bed. They should be furnished with a grooved fastening, so that the admission of air can be graduated. The openings for extraction of foul air should be near the ceiling, and as remote as possible from those admitting fresh air. They should, unless entering into the chimney-breast, be carried vertically to the roof and be provided with an aspirating cowl.

#### *Memorandum of Ambulances.*

For the conveyance of patients who are sick with infectious disease, special carriages or ambulances are necessary. The following points have to be attended to in the provision and use of such carriages:—

1. If the ambulance be intended only for journeys of not more than a mile, it may be made so as to be carried between two people, or it may be on wheels and to be drawn by hand. If the distance be above a mile, the ambulance should be drawn by a horse. Every ambulance on wheels should have easy carriage springs.
2. In the construction of an ambulance, special regard should be had to the fact that after each use, it has to be cleansed and disinfected. The entire interior, and the bed-frame and bed, should be of materials that can be washed.
3. The ambulance should be such that the patient can lie at full length in it; and the bed-frame and bed should be movable, so that the patient can be arranged upon the bed before being taken out of his house.
4. With an ambulance there should always be a person specially in charge of the patient; and a horse ambulance should have a seat for such person inside the carriage.
5. After every use of an ambulance for infectious disease, it should be cleansed and disinfected to the satisfaction of a medical officer.
6. Both in very populous districts, and in districts which are of very wide area, it may often happen that more than one ambulance will be wanted at one time; and in any district, if more than one infectious disease is prevailing, there will be an evident sanitary advantage in having more than one ambulance for use.

*Rules for Hospitals for Infectious Diseases.*

1. The medical officer is the responsible superintendent of the establishment. It is his duty to visit the hospital even at times when there are no patients, to ensure that the matron and nurse are at their post, and that everything is ready for the reception of patients.

2. The matron and head nurse ought to maintain the greatest cleanliness and to see that the beds are well aired, conveniently arranged, and always ready to receive patients. They ought also to keep the inventory of everything belonging to the hospital. They are forbidden to absent themselves together without express authority. They must carry out the orders of the doctor and be responsible for the conduct of the staff and the nurses.

3. The matron (or steward, if there is one, as in large hospitals) must be prepared monthly to present the books of accounts to the sanitary authority.

*Instructions for Nurses, Patients and Visitors.*

1. Every applicant for admission to a hospital should have a medical certificate of the disease from which he is suffering.

2. A patient can be attended by a doctor of his own choice other than the medical officer of the hospital at his own cost.

3. No person is admitted to the hospital without the permission of the medical officer.

4. No patient is permitted to leave the hospital until discharged by the medical officer.

5. The patient's clothes must be disinfected before being given up to him at his discharge.

6. Officers and servants of the hospital are not allowed to leave the hospital without authority of the medical officer; and they must first change their clothes.

The following table contains some of the most essential data relative to several of the hospitals embraced in Dr. Thorne's report. Values are expressed approximately, in United States equivalents, instead of English money.

*Statistics Presenting Cost of Construction of Isolation Hospitals and other Items.*

| DISTRICT.                     | Estimated Population. | Number of Beds. | Present Bed-rate per 1,000 of the Population. | Floor Space per Bed. | Ward Capacity per Bed. | COST OF                   |                              | Remarks.                                                                                                                                                                                                                   |
|-------------------------------|-----------------------|-----------------|-----------------------------------------------|----------------------|------------------------|---------------------------|------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                               |                       |                 |                                               |                      |                        | Hospital, excluding Site. | Bed, excluding Cost of Site. |                                                                                                                                                                                                                            |
| Berkhamstead (rural), .       | 11,000                | 8               | 0.7                                           | 144                  | 2,000                  | \$10,525                  | \$1,315                      | The addition of a second pavilion will increase the number of beds to 16, the administrative building sufficing for the requirements of increased accommodation, and the cost per bed will then amount to less than \$875. |
| Cheltenham (urban), .         | 44,000                | 35              | 0.7                                           | 144*                 | 2,300*                 | 54,160                    | 1,690                        | When the total of 56 beds has been provided the cost per bed will be reduced to \$1,090.                                                                                                                                   |
| Darlington (urban), .         | 35,000                | 44              | 1.3                                           | 144-175              | 2,000                  | 49,300                    | 1,095                        | Ward extensions are provided for.                                                                                                                                                                                          |
| Folkestone (urban), .         | 18,700                | 14              | 0.7                                           | 140                  | 2,000                  | 13,635                    | 974                          | Two other pavilions to be erected containing together 22 beds. There is also a separate small-pox hospital with 4 beds, raising the present bed-rate to 0.9 per 1,000 population.                                          |
| Lewes (combined districts), . | 11,200                | 8               | 1.1                                           | 144                  | 2,000                  | 9,620                     | 1,200                        | Two thousand three hundred dollars were spent in excavations, etc., in connection with the site. There is no disinfecting apparatus.                                                                                       |
| Middlesbrough (urban), .      | 56,000                | 32              | 0.6                                           | 122-180              | 1,620-2,100            | 33,250                    | 1,037                        | This hospital, though constructed for 32 beds, actually contains 48. The cost per bed is calculated on the number it should properly contain. Enlargement of several existing wards is provided for.                       |

\* Average.

## GLASGOW.

The following description is quoted from the official report of the trustees of the Glasgow Fever Hospital:—

“The grounds possess great natural beauty, rising gently as you approach the Clyde, where they are broken by three small glens, once the beds and sloping banks of three streams. The whole estate is well wooded, especially along the avenue and western boundary, where the rooks have recently established themselves in the tops of the old beeches. The convalescents are allowed to wander at will over the many beautiful walks, and in the summer it is one of the most pleasant sights to see the children rolling about on the grassy slopes of the glens, and the seats, placed here and there, occupied by groups of people who for the first time in the lives of many are tasting of the sweets of Nature. At the rear of the fever hospital several acres are laid out as a flower garden, with a greenhouse, from which the wards are supplied with potted plants. Flower plots are distributed here and there between the pavilions and in other open spaces. At a distance of some four miles southward, the wooded heights of the Cathkin Hills close in the horizon.”

“The whole buildings, except that occupied by the medical and nursing staff and matron, are built of brick. The wards are distributed in pairs, in thirteen totally isolated pavilions, all running north and south. They are sixty feet apart laterally, and are placed in rows of two, three, four and five, in succession from the bank overlooking the Clyde towards London Road. They have thus, to one standing in their midst, the appearance of a large, uniformly laid-out village. Each pavilion is only one story in height, with a well-ventilated basement beneath, so that the level of the ward is reached by a flight of steps. The two rows of four pavilions are separated by a range of buildings running east and west, the centre of which contains the kitchen, one story in height, and, like the pavilions, open to the roof. At either end there is another story, the eastern accommodating various stores and the dispensary; the western, the under servants' rooms. At London Road there is a main lodge controlling to the west the entrance to the small-pox hospital, and to the east, the approach to the fever hospital. At the south end of this approach is the fever lodge and enquiry rooms for patients' friends, with the Dorcas Society's stores in an attic story, and running north along the avenue, the morgue, with room for funeral parties, with entrance from the road so that hearses, etc., do not come within the hospital enclosure. Just inside this gate is the washing-house and laundry, with the suite of steam boilers to the south, a cremator for soiled beds, and the central coal depot. The boilers are three in number, double-flued, and in size seven feet six inches by twenty-six feet four inches. Further south are a smithy, carpenters' shop and fire-engine station. Southwestward, some forty yards, are the stables, ambulance

shed, etc. Still westward is a large three-story stone block, erected on the site of the old mansion house, containing eighty-four single bed-rooms for nurses, with recreation rooms on each flat. These occupy the lateral wings, while the centre is reserved for the matron and medical staff. In front of this building there is a spacious lawn, with tennis court, bounded southwards towards the Clyde by a sloping bank planted with trees."

"There are three hundred beds on the scale of 2,000 cubic feet for adults; but as a large proportion of the patients are children, for whom 1,200 feet is sufficient, a much larger number of patients can be accommodated. The dimensions of every pavilion and ward are exactly the same; but as they were erected at different times, sundry little but important differences exist. The two southern pavilions were built last, and the description of one will suffice. It has a basement eight feet from ground to floor level. The outside length, from end to end, is one hundred and sixty-eight feet; the outside breadth, twenty-six feet; the height, from ground level to ridge of roof, thirty-two feet. There are two wards, each divided into a convalescent and acute ward. A flight of steps on both sides gives access to a vestibule, from which, on one hand, are the entrances to these subdivisions, while, on the opposite side, is the pantry, opening directly off the passage, and a lobby, to the left of which are the bath-room and water-closet, and to the right a steep-room for soiled linen, these last being farthest from the wards. All these appurtenances are therefore completely isolated in a projecting annex. The entrance and annex of each ward are on opposite sides of the pavilion. On the side opposite to the entrance of the acute ward is a nurse's duty room, where there is a 'poison press' and a napery press, with chairs and a table. The front projects into the ward with sloping roof and glass sides, giving a full view of the ward. The internal dimensions are as follows: acute ward, length, 56 feet 3 inches; convalescent ward, length, 24 feet. In both the breadth is 22 feet; the height to the wall head, 14 feet 6 inches; to the roof tree, 23 feet 9 inches. The floorage of the acute ward is 1,237 square feet; of the convalescent, 528 square feet. The total cubic contents of the acute ward are 23,500 cubic feet; of the convalescent ward, 10,000. The number of adult beds is eleven for the acute and four for the convalescent ward; but in the case of children twenty cribs are allowed."

"All the flooring of the wards is of Dantzic oak, waxed. The vestibule and annex are laid with tiles. The walls are coated with Keene's cement. Some wards are oil-painted and varnished, but the more recent are treated with light blue or green distemper, which can frequently be renewed. All the woodwork is varnished. Care is taken to avoid flat surfaces giving lodgment for dust. The principal rafters are, therefore, of light T iron, and the tiles of thin rod iron."

"The heating is by hot water circulating in pipes which are led round the walls above the floor. This is derived from two hot-water tanks heated

by steam, and placed beneath the entrance hall of each ward, to which access is obtained from the outside by a stair leading to the basement. There are also open fires at either end of each ward. Pavilions with numerous windows and open to the roof are very difficult to warm sufficiently during winter. Experience at Parliamentary Road soon showed that it would be necessary to check radiation by the large glass area, and accordingly the device of double glazing each pane with an interval of three-quarters of an inch of air space was adopted. The wards at Belvidere are kept at 55° to 60° in the coldest weather. There are heating coils in the vestibule and bathroom."

"Fresh air is admitted by direct openings beneath the windows, which are numerous, so that it passes over the heating pipes. These openings are controlled by an arrangement which admits of gradation, and cannot be interfered with except by the nurse. There are skylights on opposite sides of the slope of the roof, Boyle's ventilators fixed on the ridge, and ventilating shafts alongside the chimneys, with openings controlled by movable louvres and the apex of the roof."

"The principles kept in view in furnishing are simplicity, smooth surfaces and facility of removing and cleaning. The bedsteads are wrought iron, the tables and chairs hardwood, varnished. In the children's wards, iron cribs are provided, and pigmy forms and tables suited to their size. All cupboards, presses, etc., are movable on iron rollers, like American trunks. The mattresses are stuffed with straw, the pillows with chaff. They are renewed for every new patient and whenever soiled. Wood wool was recently tried as a substitute for straw, but was found speedily to break down, and, on account of the consequent expense and larger quantity and more frequent renewal, was not adopted."

"The nurses are graded in three classes—probationers, nurses and head nurses. After a year's probation, during which she attends lectures on fever nursing given by the assistant physicians, the probationer is submitted to a written and *viva voce* examination. If she passes satisfactorily, she gets a 'Certificate of Proficiency in Fever Nursing,' first, second or third class, signed by the physician superintendent, and becomes a nurse. The wage of a probationer is £18, and advances gradually to £30, all getting two uniform suits per annum for ward use alone. To work a purely pavilion hospital such as Belvidere, all its parts distributed over a large area, and to maintain the large extent of flower garden and pleasure ground attached, requires a large staff. The distribution of coals is done by an open lorry, on which all the coal-boxes are placed and driven round the wards. The food is distributed by a covered van, divided into compartments, each of which holds the allowance for a ward. The ashes are collected daily from portable circular-covered ashbins countersunk in the ground adjacent to each ward, an arrangement which combines convenience and perfect sightliness and inoffensiveness. The whole institution is under

the care of a physician superintendent, who is assisted in the general business of the hospital by a house steward, and in the medical charge by two permanent medical assistants. These are supplemented, as occasion requires, by extra assistants. In fact, there are seldom less than three assistants, and usually in the autumn and winter there are four or five. These appointments are in great request among the best students of the Glasgow school. They are only given to qualified men, and by preference to such as have been house surgeons in either of our infirmaries. They remain from one to two years. The present physician superintendent, Dr. J. W. Allan, was appointed in August, 1875, and has contributed much by his urbanity, good management and rich experience to win and to retain the confidence which Belvidere undoubtedly possesses both with the profession and the public."

"In calculating the cost of treatment, the expenditure on the small-pox hospital is always thrown in with that on the fever hospital. There having been only rare and isolated cases of small-pox for some years, 120 beds have been constantly used for scarlet fever, and only one pavilion, barricaded off with the whole administrative buildings, for small-pox. A small staff is maintained there. The last financial year for which the accounts are made up (June 1, 1886, to May 31, 1887) may be taken as an illustration of the expenditure, number and nature of cases treated, etc. There was not a single case of small-pox treated, but £558 were expended in the small-pox hospital; £15,945 in the fever hospital; 2,790 cases were treated, including 1,270 cases of scarlet fever, 504 of measles, 204 of enteric fever, 176 of whooping-cough, 87 of typhus, 134 of erysipelas, diphtheria, chicken-pox and puerperal fever, the balance being made up of nursing mothers and cases of mistaken diagnosis. The average residence over all was 43.3 days (which is high, owing to the regulation residence being eight weeks for scarlet fever); the average daily number of patients, 332; the average cost of treatment per patient, £5 18s. This does not include interest on capital expended in building and furnishing hospitals, but does include ground, annual and all current expenditure in maintaining the whole estate and working the hospitals. Taking one year with another, the average mortality is: for typhus, 13 per cent.; enteric fever, 12 per cent.; scarlet fever, 12 per cent.; measles, 5 per cent.; whooping-cough, 12 per cent.; and over all cases, 10 per cent."

"In the northeast corner of Belvidere estate, the central washing and disinfecting establishment for the city is situated, occupying an area of 2,500 square yards. In those times when the treatment of infectious diseases was left to the Royal Infirmary, whatever disinfection was carried out at the houses of the patients was also performed by the directors. In their annual report for 1824 they refer to this fact. The first washing-house established by the authorities was a small place with a few tubs in a close off the High Street. This was opened in 1864. When Belvidere was

acquired, half of the existing fever hospital washing-house was reserved for this purpose. This soon proved inadequate, and the present separate establishment was finished, in 1883, at a cost of £8,400. It is essentially a washing-house, fitted up with the best mechanical appliances, to which the articles to be treated are driven by a service of vans. There is a Lyons disinfector, in which mattresses, clothing, etc., which cannot be washed, are disinfected, a cremator for burning straw, chaff, wool, flock and other articles, 'whose end is to be burned,' and a carpet-beating machine. It has just been resolved to spend £800 in improving the arrangements, and especially in adding appliances, devised by the sanitary inspector, for treating everything which is ultimately to be washed with a solution of bichloride of mercury, which, it is expected, will make the articles innocuous before passing them on to the washers. On an average, 1,000 articles per day are treated in one way or another."

"The hospitals, the washing-house, and the sanitary office in the city are all in telephonic connection."

#### GERMANY.

The following regulations pertain to the organization of hospitals for infectious diseases in Germany.

A. The building must be isolated and situated in an open space, if possible, away from inhabited quarters, but at such a distance that the patients may be taken to it without difficulty or distress.

B. There must be no communication between the hospital and its surroundings, and, where necessary, complete isolation must be established.

C. The beds must be separated by at least seventy-five to ninety centimeters and each patient allowed fourteen cubic meters of space. (These requirements would hardly meet the demands of modern hospital hygiene.)

Convalescents are placed by themselves. Hospitals must be provided with spare wards so that the occupied wards may be vacated from time to time and carefully purified.

D. The air of the hospital must be kept fresh and pure. The furniture must be kept perfectly clean, as well as the rooms.

E. The clothing of the patients must be separately stored and carefully disinfected before it is returned to them.

F. Convalescents must be isolated till they leave the hospital.

#### BERLIN.

##### *Hospitals for Isolation.*

At Berlin the preventive measures against infectious diseases are organized according to the regulations in force throughout the Empire.

A large hospital for isolation has been built by the corporation, composed of twenty-four detached pavilions of one story, with an additional

building for emergencies. A space is reserved for the construction of six additional pavilions.

This hospital (das städtische Krankenhaus Moabit) is situated in a space nearly open on all sides on the Moabit quarter, near to the public park, and small Thiergarten. The ground has the form of an elongated rectangle. Pavilions are built on the long sides facing east and west. The distance between each is seventeen meters, and the two sides are separated by sixty-four metres. The intermediate space is occupied by lawns, groups of trees and shrubs.

The buildings cover a surface of 10,000 square meters, of which 6,432 are occupied by buildings; the grounds, mortuaries, etc., take up the remainder.

Each pavilion contains a ward 28.25 meters in length, 6.90 meters in width, and 3.14 meters in height. Each contains thirty beds—too many in a hospital for infectious diseases, as that allows only twenty-seven cubic meters for each patient. The ward is lighted by windows in the side walls, one being placed between every two beds.

The materials employed in the construction are blocks of wood intercalated with bricks. The inside walls are lined with boards painted in oil a bright color. The floor is formed of a bed of concrete.

There are no ceilings. The roof is composed of a double layer of boards, painted in oil inside and covered outside with millboard saturated with asphalt.

A skylight runs along the middle of the roof with lateral apertures, which may be opened and shut from within.

A vestibule at one end, traversed by the entrance corridors, comprises on its right side servants' rooms and the dispensary, and on the left, the bath-room, linen-room and water-closets. All these rooms have boarded floors.

The heating is effected by means of steam-pipes connected with a boiler, which also serves for the kitchen and laundry. A large steam-pipe runs in a subterranean trench in front of the pavilions, sending a branch to each, which is subdivided into several pipes for warming the rooms and heating water for the bath-room. Three steam-pipes, two to the north and one to the south, run above the floor at a height of 0.30 meters; they are provided with taps for the regulation of the temperature. The condensed water returns to the boiler by a pipe.

Ventilation is very simply managed. Fresh air is introduced by means of fourteen openings, each eighteen centimeters wide, made in the walls of each ward at the same height as the steam-pipes, which warm the air as it enters. The impure air escapes by the lateral apertures above.

The rooms, etc., are lighted with gas; the lamps are hung below the skylight, and assist in the ventilation.

The pavilion for special isolation attached to the hospital is similarly constructed and measures 15.67 meters in length by 8 meters in width, and

3.64 meters in height. It contains three rooms separated from one another, each having three beds. A covered veranda, 2.30 meters in height, runs along the front. Large doors at each end set up a current of fresh air.

Eleven casements are placed in front of the veranda near the roof, which are removed during the summer.

A water-closet is provided for each room, placed in a vestibule, and abutting on an outside wall, being perfectly ventilated and separated from the ward by an ante-chamber.

Each of the wards has a roof of a pyramidal form, at the top of which is a ventilating-pipe surmounted with a Wolpert aspirator. The floors are made of brick covered with Metlach mosaic.

Heating is effected by steam introduced into hot-air stoves, placed in the middle of the floor, and so constructed that the heat can be regulated. The stoves are surrounded with an iron jacket.

Fresh air is supplied to the apparatus by a trench in masonry under the floor, and is warmed in passing between the stove and the jacket. The impure air escapes partly by the ventilating pipe in the roof, partly by other pipes adjoining a small tower in the ceiling of the veranda, in which are placed water-cisterns for the baths.

The rooms may also be heated by steam-pipes.

At one end of the veranda is a small enclosed room, into which linen for the wash is thrown through a trap-door; it is taken away by a door communicating with the open air.

There is a place for disinfection in the establishment through which the linen is passed.

When no epidemic prevails, part of the hospital is given up to ordinary patients. It is, however, considered preferable to nurse the latter in the städtische allgemeine Krankenhaus Friedrichshain, which is a splendid hospital built in pavilions, four of which have one story and six two stories. There are also two pavilions for isolation with two stories and another of one story exclusively reserved for diphtheritic patients.

In the department for isolation each adult is allowed a space of fifty-seven to sixty cubic meters, and each child thirty-one to forty-two cubic meters.

The pavilion for diphtheria is warmed by steam, but the general method is a combination of heating by means of hot-water apparatus connected with the ventilation. Each ward has also chimneys open in the summer and autumn.

In order to assist ventilation the smoke-pipes pass through the ventilating shaft.

The removal of persons suffering from infectious diseases is entrusted to contractors charged with the maintenance of the necessary carriages, the use of public carriages being forbidden to such patients in virtue of an official order of the 7th of February, 1887.

## PARIS.

No satisfactory system for the treatment of persons sick with infectious diseases in hospitals specially designed for this purpose has yet been effected, but a commission was appointed to investigate the subject, and reported in June, 1887, to the municipal council. Thus far, persons attacked with infectious diseases have been received into all hospitals, except small-pox patients, who were only admitted to the hospitals of Saint Louis and Saint Antoine, which had isolated buildings for their accommodation. In the other hospitals the infected are also isolated, but experience has proved that the measures taken for that purpose have not been effectual, and it too often happens that infection is propagated within these establishments. Statistics also show that there has been an increase in the deaths from infectious diseases in Paris, while they have sensibly diminished in other cities where isolation is better organized.

There is a station at the Hotel Dieu in connection with the transport of infectious cases, in which are kept two horses, two carriages and a driver. When any person ill with a contagious disease requires to be taken to the hospital, notice is sent to the nearest police station, whence it is transmitted to the Prefecture, who then sends orders to the Hotel Dieu. The disinfection of carriages is prescribed by the regulations, but this duty is left to the driver, without supervision.

The plan already mentioned provides for two ambulance stations, one on the right bank of the Seine, near the Hospital of St. Antoine, and the other on the left bank, near the Hospital for Sick Children. Each of these stations is to have twelve carriages for removal of the sick. Two will be reserved for small-pox, two each for measles, diphtheria, scarlet fever and typhoid fever, and the last two will be reserved for other diseases— whooping-cough, erysipelas, etc. The carriages used for one disease are never to be used for another. Each coach-house must be divided into six compartments in order to prevent mistakes. The stable will be arranged for six horses, though it will not be necessary to keep more than two in them under ordinary circumstances.

A certain number of nurses will be assigned to each ambulance to accompany the patients. They will live in the adjoining hospital and give their services in turn.

The staff of the station will consist of a chief officer, two coachmen, one of whom must be married, and a servant, who may be the wife of the latter. All these persons will live on the premises, and the staff, as well as the nurses, will be boarded there. The estimated cost of construction of each station is about \$14,000, and that of each carriage about \$500. Each is to be provided with a seat for the nurse, near the pillow of the patient, and a drawer for clothes and linen. After each journey the carriage is to be thoroughly washed. The stations are to be connected by telephone with the Relief Board and the Prefecture.

*Hospitals.*

As a part of this general plan, four hospitals are to be erected near the gates at the entrance of the city. Two will be devoted to small-pox, and one each to diphtheria and to measles. The first are designed for seventy beds in each. The plan provides for reserving a plat of ground near by, so that in case of need supplementary pavilions may be constructed with accommodations for more than eighty more patients. This ground is to be levelled, covered with asphalt and drained, so that temporary buildings can be put up in a few days. If further accommodation is required, it is proposed to build a hospital for convalescents at Creteil, southwest of Paris, on ground belonging to the Relief Board.

A hospital for diphtheria also forms a part of the plan, to be erected near Bicêtre, at the south end of the city.

The following figures show the special need for arresting the progress of diphtheria and measles in Paris :—

*Mean Death-rate from Diphtheria per 10,000 Inhabitants, Paris.*

|                    |           |      |
|--------------------|-----------|------|
| From 1865 to 1869, | . . . . . | 4.32 |
| " 1870 to 1874,    | . . . . . | 4.72 |
| " 1875 to 1879,    | . . . . . | 8.88 |
| " 1880 to 1884,    | . . . . . | 9.26 |
| " 1885 to 1887,    | . . . . . | 7.68 |

*Mean Death-rate from Measles per 10,000 Inhabitants, Paris.*

|                    |           |      |
|--------------------|-----------|------|
| From 1865 to 1869, | . . . . . | 3.18 |
| " 1870 to 1874,    | . . . . . | 3.35 |
| " 1875 to 1879,    | . . . . . | 3.72 |
| " 1880 to 1884,    | . . . . . | 4.90 |
| " 1885 to 1889,    | . . . . . | 5.71 |

Scarlet fever does not appear to have found a congenial soil in Paris, the average mortality per 10,000 from this cause being but 0.9 as compared with 1.7 in London, 1.2 in Edinburgh and 3.2 in Berlin. Measures for its restriction there do not therefore appear to be so imperative as in the case of the infectious diseases already named.

With the view of diminishing the spread of whooping-cough it has also been proposed to found a great isolating establishment, including a school and a hospital.

The public disinfecting stations form a part of the general plan for the prevention of the spread of infectious diseases. Those of Paris and Berlin are most thoroughly equipped, and managed in the most effective and systematic manner. Their description, however, does not come within the scope of the present paper.

Later information upon the subject of isolation of contagious diseases in Paris may be found in a paper contributed to the International Congress of Charities, Correction and Philanthropy at Chicago in June, 1893, by Drs. Herbert and Hogg of Paris.\*

The following summary is presented in that paper of the facilities which are afforded in Paris for the isolation and treatment of hospital patients suffering with contagious diseases. The hospitals providing such facilities are six in number : —

The *Aubervilliers Hospital* possesses separate buildings for small-pox, measles, scarlet fever, erysipelas, diphtheria and doubtful cases ; in all, 184 beds.

The *Hospital Trousseau*. Isolation wards are established for children with diphtheria, measles and scarlet fever (181 beds).

*Hospital "des Enfants Malades"* (Enfants Jésus), which is a hospital for children, receives diphtheria and scarlet fever patients (52 beds).

In addition to these the following hospitals are provided with isolation rooms : *Lariboisière*, 7 beds ; *La Pitié*, 5 beds ; *La Charité*, 3 beds.

All of these taken together furnish a total of 332 beds.

#### SWEDEN.

In Sweden, local public health administration is in charge of a Commission of Hygiene, in the towns (Helsövardsnämnd) ; and in rural districts the Communal Council is entrusted with sanitary functions. These have been organized by laws of 1874 and 1885.

During the prevalence of an epidemic of infectious disease the Commission must attend to the following regulations : —

1. The immediate removal of the patient to a special hospital, a place isolated for the purpose, unless the transport should endanger the life of the patient. He may remain in his own dwelling if he can be nursed according to the regulations prescribed by the Commission.

2. The immediate disinfection of the house, clothing, bedding, etc., of the patients who have died, recovered or been sent to the hospital.

3. Patients are not to be removed in public carriages ; stretchers, sedan chairs, etc., are disinfected after use.

4. Clothing of the patients, and anything belonging to the hospital which has been lent or sold, are to be disinfected.

Persons suffering with epidemic or infectious diseases cannot refuse to be removed to the special hospital unless life would be endangered, or they can be nursed in a place properly isolated, at their own expense.

When two infectious diseases prevail at the same time, two special hospitals should be established, or, at least, a properly isolated portion must be set apart for the treatment of one class of patients.

---

\* Hospitals, Dispensaries and Nursing. Papers, Discussions, etc., at Congress of Charities, Correction and Philanthropy, June, 1893. New York, 1894.

*Stockholm.*

Population about 225,000. In Stockholm the plan presented in 1884, by Dr. Linroth, Chief Medical Officer, for the purpose of organizing the treatment of infectious diseases in the city includes —

1. A hospital placed at one end of the city, organized in a pavilion system, and comprising —

|                                                                              |          |
|------------------------------------------------------------------------------|----------|
| A building for small-pox, with . . . . .                                     | 20 beds. |
| A building for typhus fever, with . . . . .                                  | 20 “     |
| A building for scarlet fever, with . . . . .                                 | 35 “     |
| A building for diphtheria, with . . . . .                                    | 28 “     |
| A building for measles, with . . . . .                                       | 35 “     |
| A building with, at least, ten small observation rooms, each having one bed. |          |

A building for the staff, containing also rooms for the medical officers of the establishment.

Buildings for offices, such as kitchen, laundry, place for disinfection and the burning of straw, stables, coach-houses and ice-houses.

A place should be reserved on the same ground for two temporary hospitals, the plans and drawings for which must be quite ready so that they can be erected without delay in case of need.

2. A branch establishment at the other end of the city, organized after the same system, and comprising —

|                                                            |          |
|------------------------------------------------------------|----------|
| A building for scarlet fever, with . . . . .               | 30 beds. |
| A building for measles, with . . . . .                     | 25 beds. |
| A building for the staff, and two rooms for special cases. |          |
| A building for the offices of the establishment.           |          |

3. An establishment situated in the group of islands on this side of Vaxholm, intended to receive infectious patients who have arrived by sea, and comprising a pavilion with fifteen beds; a place for disinfection; a building for the staff and officers.

4. A place for disinfection within the city for the healthy members of families exposed to infection, and for suspected clothing. The number of beds available should be one hundred and forty-eight in the large hospital, fifty-seven in the branch establishment and fifteen in the island hospital, in all two hundred and twenty beds.

Dr. Linroth is of opinion that typhoid fever may safely be treated in the other hospitals of the city as in previous years.

The construction of a new isolation hospital on the above plan was only begun in 1890. The hospital comprises five pavilions, comprising altogether one hundred and sixty-two beds, a building with eight observation

rooms, a building for the administration and for the doctor, one for cooking, a laundry, mortuary, etc.

Before this time the old hospitals were utilized, temporary buildings being erected for special requirements.

These are constructed of double boards. The interstices of the walls, floor and ceiling are filled up with charcoal.

A barrack on this model was erected in ten days in the park of Bellevue near Brunsviken, when an epidemic of small-pox was threatened. The expense amounted to about £700.

A permanent erection has been constructed on the ground of the hospital Saint Maria to serve as a place for isolation. Its total length is 32.30 meters and the width 7.50 meters. Its height is 15.50 meters between the ground and the ridge. The front, which looks towards the west, is flanked by a fore-court eight meters in length by 5.5 meters in width. The sides are made of boards 7.5 centimeters thick, wainscoted and lined with mill-board outside and inside. The roof is of mill-board covered with asphalt.

The building contains two wards, with thirteen beds in each. The space between the wards is occupied by a room for the nurse, a linen-room, and a small kitchen for making drinks. Behind the vestibule adjoining the wards, which can be divided into parts, is a fore-court in which are placed the latrines and the bath-room. The floors of the wards are made of asphalt, laid on a bed of cement, which is placed on the ground, covered with a bed of broken stones and gravel. The other rooms have also asphalt floors, excepting the nurses' room.

The walls and ceilings are painted in oil throughout the building, in order that they may be easily cleaned. Each bed in the wards has 7.20 square meters of floor space and 30 cubic meters of cubic space. The windows are made in the side wall of the ward, and look east and west, there being eleven in each ward. The windows are two meters in height by one in breadth, their total surface being about one-fourth of the floor. The establishment possesses a gas and water service. There are two baths made of copper in the bath-room. The latrines are arranged on the system of movable tanks used in the city, but in such a way that the urine flows away separately by a subterranean pipe. In the closets there are also cisterns in zinc for the soiled linen, a current of water continuously passing through them from top to bottom, and discharging into the sewer. The speed of the current is regulated at pleasure.

In this way all risk from the handling of dry linen worn by the infectious patients is avoided. The linen is not taken from the water and wrung until the moment when it is to be sent to the wash. The cisterns have lids locked with a key.

Heating and ventilation are effected by means of a kind of stove with an iron casing lined with fire-proof bricks. The casing does not come higher

than the middle of the stove, and is 6 centimeters from it. The total height of the apparatus is 3.60 meters, the exterior diameter, 0.60 meter; the heated surface, 7 square meters.

The fresh air, entering by a pipe sixty centimeters by thirty, arrives at the bottom of the stove and is heated in passing between the stove and the casing. The ventilating-pipe is provided with a sliding valve.

The stoves are arranged for slow combustion, fed at long intervals during the day, and kept locked.

The impure air escapes by pipes heated in the chimney, each discharge pipe having an opening near the floor for ventilation in winter and one under the ceiling for summer; the valves of these openings are enclosed that they may be out of reach of the patients.

The upper sash of two opposite windows in each ward is provided with hinges below, so as to open within, and has an iron plate on each side.

All the air-pipes are arranged so as to be easily cleaned.

During the summer more thorough ventilation may be secured by a water ventilator on Trentler and Schwartz's systems, fixed in the roof, above the centre of the building. This ventilator is put into communication with the wards and the outer air in such a way that air may be admitted or excluded at pleasure by opening or shutting valves.

The cost of this barrack is about £1,440.

The city keeps a special carriage for the removal of infectious patients. It is lined inside with varnished wood, which can be easily cleaned after each journey.

#### DENMARK.

##### *Copenhagen.*

The wards of Blegdams Hospital are fitted up with special care for the treatment of patients with infectious diseases. There are eight one-storied pavilions, two for twelve patients each, six for twenty-six each, and a two-storied pavilion for seventy-eight patients; besides, there are some movable marquees (felt tents of Docker's patent), with accommodations for fifty patients. The general arrangement of the hospital is shown in the accompanying plan. The one-storied pavilions belong to several systems. One of these is especially distinguished by its heating and ventilating system, planned by Mr. Julius Thomsen, Professor of the University and President of the Polytechnic Academy. In outline it is in each of two entirely similar halves, as follows: fresh air is conducted from wells at a proper distance from the building to an air chamber in its cellar, from which it is conducted under the floor of the sick ward, into which it ascends through three openings in the floor. In the cellar a fire is kept up all the year round; during the cold season the draught from the furnace is conducted to a chimney in the centre of the building through a calorifere placed in the air-chamber; hereby the fresh air gets a suitable temperature, while the

draught in summer is conducted directly to the chimney, without passing the calorifere. The chimney will always thus be able to exhaust the vitiated air of the sick ward, which is effected by means of channels leading

PLAN OF BLEGDAMS HOSPITAL, COPENHAGEN

to the chimney from openings in the walls of the ward at various heights from the floor. The draught in the fireplace, in which the consumption of fuel naturally varies according to outside temperature, can be regulated with a simple mechanism from the cellar, as well as from the sick ward, so that it goes partly through the calorifere, partly directly to the chimney, and that an increase of one passage corresponds to a diminishing of the other. In the same manner the exhaust can be regulated; its strength can be read from an anemometer in the ward, and it may be regulated or entirely stopped, according to circumstances. The nurses are thus at all times able to control the temperature and renewal of air. The above-mentioned two-storied sick ward of Blegdams Hospital was just completed at the expiration of 1890, and represents a high-class modern-hospital technique. The principles on which the new operating room in the Commune Hospital, above described, was built are in every essential also used in this building. Its baths, kitchens, closets and other accessories are in most perfect harmony with the principles described above.

## III.

The following summary embraces the returns of diseases "dangerous to public health" made to the State Board of Health under the provisions of chapter 302 of the Acts of 1893. Since the act in question did not specify the diseases intended to be reported to the Board (except small-pox), the Board issued a circular, in which it expressed its opinion as to the particular diseases which should be reported under the provisions of this act. They were the following: *small-pox, scarlet fever, measles, typhoid fever, diphtheria, membranous croup, cholera, yellow fever, typhus fever, cerebro-spinal meningitis, hydrophobia, malignant pustule, leprosy and trichinosis.*

The report of 1893 embraced the returns of the fractional year only which immediately followed the enactment of the statute, while those of 1894 were for a full year.

The whole number of cases of infectious diseases reported in 1895 was 21,307, which were divided as follows:—

|                                                   |        |
|---------------------------------------------------|--------|
| Reported cases of small-pox, . . . . .            | 1      |
| Reported cases of diphtheria and croup, . . . . . | 7,806  |
| Reported cases of scarlet fever, . . . . .        | 6,194  |
| Reported cases of typhoid fever, . . . . .        | 2,438  |
| Reported cases of measles, . . . . .              | 4,868  |
| Total, . . . . .                                  | 21,307 |

The summary for the years 1893, 1894 and 1895 is as follows:—

|                   | REPORTED CASES OF |                       |                |                |          |
|-------------------|-------------------|-----------------------|----------------|----------------|----------|
|                   | Small-pox.        | Diphtheria and Croup. | Scarlet Fever. | Typhoid Fever. | Measles. |
| 1893, . . . . .   | 35                | 1,109                 | 2,914          | 1,525          | 1,303    |
| 1894, . . . . .   | 181               | 4,178                 | 6,731          | 2,372          | 2,133    |
| 1895, . . . . .   | 1                 | 7,806                 | 6,194          | 2,438          | 4,868    |
| Totals, . . . . . | 217               | 13,093                | 15,839         | 6,335          | 8,504    |

## HEALTH OF TOWNS.

---

Under this title it has been customary to present a digest of the annual reports of the local boards of health which have been received at the office of the State Board of Health.

Very few of the smaller towns (such as have populations of less than 2,000 inhabitants) publish separate reports of the local boards of health. The reports which we receive are, therefore, mainly those of the cities and large towns.

The most prominent topics which appear in these reports are the increased care devoted to the subject of the notification of infectious diseases, and their prevention by isolation, disinfection and vaccination, the need of sewerage and efficient methods of disposal in towns where no systems are in existence, the inspection of plumbing and registration of plumbers, and the disposal of the garbage and the refuse of houses and of streets.

The subject of the notification of diseases has been considered at an earlier place in this volume.

The following table contains the statistics of cases of diphtheria, scarlet fever, typhoid fever and measles reported to local boards of health, as compiled from the annual reports of such boards, which have been forwarded to the office of the State Board, since the close of the calendar year 1893. In parallel columns are also presented the deaths from the same causes, as given in the same reports.

| WORCESTER, . . . . .      | 123                   | 38      | 179            | 10      | 143            | 31      | 1,112    | 16      |
| Totals, . . . . .         | 2,919                 | 926     | 7,420          | 654     | 2,457          | 492     | 6,290    | 98      |

From the comparison of these figures, the relative fatality of each disease during the year in these cities and towns may readily be ascertained. The columns of deaths may be considered as quite accurate, while the reported cases are probably somewhat less than

the actual numbers, in consequence of a small percentage of neglect or failure to report. The figures are as follows :—

|                                                        |                |
|--------------------------------------------------------|----------------|
| Reported cases of diphtheria and croup, . . . . .      | 2,919          |
| Registered deaths from diphtheria and croup, . . . . . | 926            |
| Fatality, . . . . .                                    | 31.7 per cent. |
| Reported cases of scarlet fever, . . . . .             | 7,420          |
| Registered deaths from scarlet fever, . . . . .        | 654            |
| Fatality, . . . . .                                    | 8.8 per cent.  |
| Reported cases of typhoid fever, . . . . .             | 2,457          |
| Registered deaths from typhoid fever, . . . . .        | 492            |
| Fatality, . . . . .                                    | 20.0 per cent. |
| Reported cases of measles, . . . . .                   | 6,290          |
| Registered deaths from measles, . . . . .              | 98             |
| Fatality, . . . . .                                    | 1.6 per cent.  |

The following summary contains the figures for each of these diseases for the years 1891, 1892 and 1893 :—

*Reported Cases of Infectious Diseases.*

|                           | DIPHTHERIA AND CROUP. |       |       | SCARLET FEVER. |       |       | TYPHOID FEVER. |       |       | MEASLES. |       |       |
|---------------------------|-----------------------|-------|-------|----------------|-------|-------|----------------|-------|-------|----------|-------|-------|
|                           | 1891.                 | 1892. | 1893. | 1891.          | 1892. | 1893. | 1891.          | 1892. | 1893. | 1891.    | 1892. | 1893. |
| Reported cases, . . . . . | 2,444                 | 3,033 | 2,919 | 4,517          | 6,112 | 7,420 | 2,414          | 1,892 | 2,457 | 5,861    | 783   | 6,290 |
| Deaths, . . . . .         | 575                   | 891   | 926   | 151            | 281   | 624   | 460            | 435   | 492   | 84       | 31    | 96    |
| Fatality, . . . . .       | 23.5                  | 29.2  | 31.7  | 3.3            | 4.6   | 8.8   | 19.0           | 23.0  | 20.0  | 1.4      | 4.0   | 1.6   |
| Mean of three years,      | 28.5                  |       |       | 6.8            |       |       | 20.5           |       |       | 1.6      |       |       |

The cities and towns embraced in this list were 70 in number, and comprised about three-fourths of the population of the State. They were nearly identical with those which furnished reports in 1892.

The number of reported cases of diphtheria was eighty less than that of 1892, and the percentage of fatal cases was slightly larger.

The reported cases of scarlet fever exceeded those of 1892 by 1,308, while the fatality was 8.8 per cent. or nearly double that of the preceding year.

The reported cases of typhoid fever were greater than those of 1892 by 565, but the fatality was less, being 20 per cent. as compared with 23.0 in the preceding year.

The reported cases of measles were eight times as many as those of 1892, but the fatality was less than half as great, being 1.6 per cent. as compared with 4.0 in the preceding year.

The following figures present the fatality from diphtheria, scarlet fever and typhoid fever as reported by the Local Government Board of England for the years 1890, 1891 and 1892.

|                          | 1890. | 1891. | 1892. |
|--------------------------|-------|-------|-------|
| Diphtheria, . . . . .    | 25.5  | 23.7  | 23.6  |
| Scarlet fever, . . . . . | 8.0   | 5.8   | 4.4   |
| Typhoid fever, . . . . . | 19.9  | 20.8  | 17.8  |

#### AMESBURY.

There have been many less complaints entered this year than last, eighty-two cases as against one hundred and fifty. Most of these were promptly abated on the attention of the property owners being called to the unsanitary conditions, therefore little expense was incurred to have official notices served.

There was some delay in abating the odor from the old soap factory, but the exigencies of the business made it almost unavoidable.

The Board would again call the earnest consideration of the voters of the town to the utility and economy of sewerage the town, as per plan now on file; if not the whole, at least a part should be done every year.

Scarlet fever at first showed itself in a mild form, but has gradually assumed a more malignant type, with a death rate of sixteen per cent. of reported cases. To stay the spread of this dread disease, the Board has promptly placarded every house in which the disease has been reported, and given full instructions as to the importance of isolation and proper disinfection. Some physicians and most heads of families have been dilatory in reporting the cases, and some were not reported at all. The State law requires such reports to be made, and imposes heavy fines for neglect. The school committee had the public schools closed for some weeks to stay the progress, but with no perceptible benefit, as two days before re-opening them there were seven new cases reported. The necessity of isolation in this disease is beyond question, and the all important step to be taken, if followed by efficient disinfection.

Two cases of supposed glanders in horses have been reported to the Board, one case being imported. The matter was immediately investigated by the Board and a veterinary surgeon from Boston, and the animal was satisfactorily disposed of at the phosphate factory.

## ARLINGTON.

In the absence of a regularly elected Board of Health, the selectmen, under the statutes, constitute the Board. As our town increases in population, and dwellings are erected nearer together, the importance of an alert and competent Board of Health is evident. On all our streets a greater or less portion of the land is used for cultivation. This results in the use of various forms of fertilizers, which, while not always dangerous to health, are very objectionable — whole neighborhoods at times being rendered uncomfortable by the unloading of the refuse from the city.

The keeping of swine within the limits of the town should be restricted to places remote from the densely inhabited portions.

We suggest that a separate Board of Health be elected by the town, selected from those citizens who are especially familiar with sanitary matters.

## ATTLEBOROUGH.

In accordance with the requirements of the Public Statutes, the Board of Health makes an annual report to the town. This report should include an account of the duties performed by the members, such suggestions for the physical welfare of the town as occur to them as the results of their experience, and tables of vital statistics which, when compared with reports of former years, indicate the way the town is growing and suggest opportunities for its sanitary improvement.

Less complaints were received this year than usual. In fact, householders are now generally informed as to the requirements of the Board and gladly conform to them. No serious epidemic has occurred.

Measles became so prevalent that the Board requested the school committee to exclude from the public schools all pupils coming from homes where there were such cases. This, being an innovation, caused unfavorable criticism from the public and even from physicians in town, but singularly enough, by this action the local Board only anticipated by a few months what is now required by the statutes, viz., that measles shall be included in the list of diseases "dangerous to the public health," and consequently to be especially guarded against.

## AYER.

The most notable occurrence in connection with the health of the town, during the year, was an epidemic of scarlet fever. The lower grades of the public schools were closed for several weeks in December with little apparent effect in checking the spread of the disease. The disease was probably spread in many instances by cases so mild they were not recognized.

## BARRE.

It is a notable fact relative to the health of Barre, that, in a total of thirty-five births and thirty-six deaths, there were no deaths of infants, and no death was reported of any person under thirty years of age.

## BEVERLY.

There was free vaccination of 1,374 patients, and the issuing of certificates to the same.

In view of the fact that the town has voted to put in a system of sewerage, the Board would most earnestly recommend that the town adopt the State plumbing law so that in the future the citizens will receive the full benefit of the sewer.

They would also call attention to the daily increasing demand for the adoption of some system for the collection of garbage, swill and ashes. At the present time the greater part of the swill is mixed with ashes and then dumped on some of the various dumps in and about the town, thus creating a very undesirable state of affairs in such locations.

## BOSTON.

The total number of deaths during the year was 11,710, an increase of 474 over the preceding year. The death-rate per 1,000 inhabitants for the year is found to be 24.02. The prevalence of pneumonia during the year assumed a character unequalled in the registration of vital statistics in this city. In 1851 its percentage to the total mortality was 7.75; in 1893 it was 13.15 per cent., or a total of 1,540 deaths from this cause alone. It is gratifying, however, to be able to state that the percentage of the total mortality from zymotic causes is less by .49 per cent. than for the year 1892, or 17.43 per cent. of the total number of deaths. The deaths from diphtheria increased 62, while the deaths from scarlatina decreased 14, as compared with the preceding year.

*Infectious Diseases.*

*Small-pox.* — On Oct. 30, 1893, after an interval of fourteen months, a case of small-pox occurred in Ward 6. The patient, a boy eleven years old, who arrived in Boston, October 15, on the "Catalonia," must have contracted the disease on that steamer. On November 6 a second case occurred. The case was found in Ward 22, and was directly traceable to the "Catalonia." This patient was removed to the hospital, and as he was unvaccinated he had a severe attack of the disease. This case gave rise to two others occurring in this man's family. As the two last patients had been vaccinated they were not very ill, and remained at the hospital only a short time. On November 13, in Ward 13, three cases occurred in one family, which were

directly traced to a mild attack of the disease which must have been contracted on the "Catalonia." These three patients, together with the person who arrived on the "Catalonia," were removed to the hospital, where they all recovered. The unvaccinated were quite ill; the vaccinated were not seriously ill. On November 18 a case occurred in Ward 14. The patient, a little girl about three years old, contracted the disease from a mild case in a person who arrived in Boston on the "Catalonia." On December 7, 8 and 9 eight cases occurred in Ward 19, which were contracted from an unrecognized and mild attack of the disease. A case occurred on December 8, in Ward 18, the origin of which could not be traced. From Dec. 10, 1893, to Jan. 5, 1894, eleven cases occurred which could be directly traced to the mild case in the family living in Ward 19, which has been previously mentioned. On December 13 a case occurred in Ward 14, which could be directly traced to a previous case.

From Oct. 30, 1893, to Jan. 31, 1894, there were in all thirty-six cases. The percentage of deaths among the unvaccinated has been 29.62. No vaccinated person has died, and no vaccinated person has been seriously ill. A mother nursed her infant, who had the disease, during the whole course of the attack, but as the mother had two perfectly characteristic scars she did not contract the disease. Two vaccinated children, relatives of a patient, were constantly exposed from three to four weeks to the disease and did not become ill.

*Vaccination.* — The number of cases of small-pox having increased in November, it was thought best to offer free vaccination in those sections of the city where cases of this disease were most frequently found, and there were in round numbers 100,000 vaccinated.

Early in November, while vaccinating among school children in South Boston, the Board personally discovered the fact that many children were attending the public schools without ever having been vaccinated, and these facts were subsequently communicated to the School Committee, under date of Nov. 28, 1893. Fifty-nine thousand four hundred and eighty-eight pupils have been examined; there have been 4,120 primary vaccinations; 10,152 re-vaccinations; and the number of pupils refusing vaccination and presenting insufficient evidence of having been vaccinated is 1,678.

*Diphtheria.* — The Board of Health has repeatedly asked for an appropriation with which to increase its care for the uncontrolled cases of diphtheria and scarlet fever, and it has as often been refused. The Board would like to have all cases seen by its own physicians or agents, held under proper surveillance while at home, and released from isolation only on the certificates from the same physicians or agents. We would like to aid in having all doubtful cases of sore throat decided by expert bacteriological examinations, and have all cases of diphtheria discharged from isolation by means of the same tests, or after a prolonged isolation when all local and general symptoms of the disease have disappeared. To do this the department

must have more medical agents, and have its present medical officers relieved from duties now performed for other departments of the city.

We have long since been satisfied that the welfare of the schools and the community at large demands better protection against the spread of contagious diseases, and that through additional medical agency alone can we hope to give such protection.

For this purpose the Board of Health recommended to the School Committee the adoption of the following regulations in response to a request from the School Committee:—

First: That no pupil be admitted to any public schools without a certificate from \_\_\_\_\_ that such pupil bears the physical evidence of having had a disease known as vaccinia.

Second: For the return of any pupil to school after suffering from small-pox, scarlet fever, diphtheria, measles, or whooping-cough, a certificate should be required from \_\_\_\_\_ that the pupil has lost all power to communicate to others the disease from which he has been suffering, and that all infected articles of his household have been disinfected to the satisfaction of the Board of Health. For the continuance of any pupil in school in whose family or in whose proximity there is a case of small-pox, scarlet fever, diphtheria, or measles, or any undestroyed infection or contagion from said diseases, there should be required a certificate from \_\_\_\_\_ setting forth the fact that the patient is safely removed from the danger of contracting and of conveying the disease.

When a child is known to have been exposed to the infection of small-pox, scarlet fever, diphtheria, or measles, it should return to school only on certificate of \_\_\_\_\_ that the period of incubation belonging to the disease to which he has been exposed has passed.

#### *Houses Vacated.*

During the year one hundred and eighteen houses have been ordered vacated for various causes, the chief complaints being general unsanitary conditions and want of repair. These houses were for the most part tenement-houses located in different sections of the city.

#### *Tenement and Lodging House Inspection.*

During the night visits of the inspectors the present winter, many cases of overcrowding were discovered in tenement-houses in the poorer sections of the city.

This the Board has been obliged to remedy by ordering the removal of all the occupants of such tenements, as it is obviously impossible for the Board to determine which ones should be allowed to remain, and which compelled to go. This difficulty, however, was in many cases solved by the occupants themselves, and as soon as the number of occupants became reduced to a satisfactory limit the Board rescinded its order to vacate the

premises if other sanitary requirements were complied with; in a few instances, however, the premises had to be entirely vacated before a satisfactory condition was reached.

The cheap lodging-houses have been frequently visited, and in most cases all requirements of the Board were complied with.

*House to House Inspection.*

|                                                       |       |
|-------------------------------------------------------|-------|
| Whole number examined, . . . . .                      | 382   |

| Defective drains found in, . . . . .                  | 122   |
| Defective trapping found in, . . . . .                | 107   |
| Privy-vaults found, . . . . .                         | 3     |
| Offensive vaults found, . . . . .                     | 3     |
| Damp or unclean yards, . . . . .                      | 8     |
| Damp or unclean cellars, . . . . .                    | 14    |
| Using furnaces, . . . . .                             | 190   |
| Furnaces without proper air-supply, . . . . .         | 18    |
| Using steam-heat or hot water, . . . . .              | 28    |
| Water-closets found in, . . . . .                     | 377   |
| Offensive water-closets found in, . . . . .           | 18    |
| Ventilation to soil-pipe or drain found in, . . . . . | 250   |
| Offensive cesspools found, . . . . .                  | 13    |
| Percentage of defective drains, . . . . .             | 31.94 |
| Percentage of defective trapping, . . . . .           | 28.01 |
| Percentage of unventilated drains, . . . . .          | 34.55 |

*Pollution of Charles River.*

In the fall of 1892 a complete inspection and report were made by a corps of inspectors from this office of all the drainage which was a source of pollution to the Charles River. This report includes all that part of the river located in Ward 25, and embraces not only the public sewers but also all private drains, the discharges from which, either directly or indirectly, eventually find their way into the river. At the time of inspection, in 1892, there were 232 private drains reported as discharging directly or indirectly into the river.

*Public Baths.*

The following table shows the number of bathers at the public baths:—

|                                  | 1892.     | 1893.     |
|----------------------------------|-----------|-----------|
| Total men and boys, . . . . .    | 908,889   | 825,614   |
| Total women and girls, . . . . . | 216,947   | 181,864   |
| Total of both sexes, . . . . .   | 1,125,836 | 1,007,478 |

*Disinfection.*

The following tables show the work of disinfection during the year : —

|                                          |       |                               |       |
|------------------------------------------|-------|-------------------------------|-------|
| Diphtheria, . . . . .                    | 1,307 | Infected books, . . . . .     | 23    |
| Scarlet fever, . . . . .                 | 2,235 | Infected carriages, . . . . . | 28    |
| Typhoid fever, . . . . .                 | 3     | Cancer, . . . . .             | 2     |
| Measles, . . . . .                       | 17    | Miscellaneous, . . . . .      | 2     |
| Small-pox, . . . . .                     | 20    |                               |       |
| Infected clothing and bedding, . . . . . | 79    | Total, . . . . .              | 3,716 |

Number of rooms, 6,429.

|                      |        |                          |         |
|----------------------|--------|--------------------------|---------|
| Streets, . . . . .   | 429    | Water-closets, . . . . . | 9,522   |
| Places, . . . . .    | 743    | Passageways, . . . . .   | 5,510   |
| Courts, . . . . .    | 564    | Urinals, . . . . .       | 389     |
| Alleys, . . . . .    | 3,803  | Vacant lots, . . . . .   | 525     |
| Yards, . . . . .     | 17,415 | Filthy sheds, . . . . .  | 7,509   |
| Vaults, . . . . .    | 4,413  | Filthy rooms, . . . . .  | 2,965   |
| Cellars, . . . . .   | 10,656 | Sinks, . . . . .         | 9,739   |
| Cesspools, . . . . . | 18,723 |                          |         |
| Gutters, . . . . .   | 11,004 | Total, . . . . .         | 103,909 |

Material used: bichloride of mercury, 1,550 pounds; chloride of lime, 54 casks; sulphur, 31,671½ pounds; copperas, 22 barrels; and 7 barrels of other disinfecting powder.

*Nuisances.*

The total number of nuisances abated during the year is 8,447.

In addition to the foregoing there have been 930 complaints investigated where action by the Board was found to be unnecessary.

*Report of Physician to the Board of Health.*

There have been 4,332 persons vaccinated, and certificates of vaccination have been given to 3,416 children for their admission to the public schools.

At the request of the Civil Service Commission three hundred and eighty-eight men have been examined for appointment in the Police and in the Fire Departments.

The bodies of six hundred and nineteen persons dying without a physician in attendance have been examined. These cases comprise principally those who die from chronic diseases, where there has been no medical care for months previous to death, and those who die suddenly from natural causes. In these a careful external examination is made, the symptoms learned, and a diagnosis, sufficiently accurate for all practical purposes, reached.

Ninety-six cases of eruptive disease reported as small-pox have been examined. Of these, twenty-six were found to be small-pox, and the patients—five men, thirteen women and eight children—were removed to the small-pox hospital on Canterbury street, where twenty-two recovered. The manifest importance of a bacteriological investigation as a means of diagnosis in doubtful cases of diphtheria is becoming more and more evident, and of no less importance, as far as the well-being of the community is concerned, is the bacteriological investigation of cases after apparent recovery from diphtheria. In an endeavor to diminish the prevalence of this disease, the two most important factors are: first, the recognition of mild and doubtful cases; second, the actual disappearance of the specific germs of the disease, which can only be recognized by means of a bacteriological investigation.

*Report of Port Physician.*

During the entire year all vessels arriving from the following ports were stopped at this quarantine for inspection: from all ports in Europe; from the Western, Madeira, Canary, or Cape Verde islands; from the Mediterranean sea or straits thereof; from the west coast of Africa or around the Cape of Good Hope, and from Central and South America.

From the first of June, vessels from the West India, Bahama, or Bermuda islands, and Mexico were stopped for inspection.

From the first of June to the first of November, all vessels arriving from any port in the United States south of Virginia were inspected at this quarantine.

Eight hundred and sixty-one vessels were boarded during the year.

Number of vessels disinfected, eight; one of which was a schooner and the remainder were steamers.

Number of persons removed from vessels for sickness, seventeen.

Number of persons vaccinated, 2,855.

The new bath-house and disinfecting cylinder were used for the first time April 1, and they both worked satisfactorily.

*Report of Inspector at Abattoir.*

*Animals Killed.*

|                   |               |
|-------------------|---------------|
| Cattle, . . . . . | 34,521        |
| Calves, . . . . . | 6,540         |
| Sheep, . . . . .  | 63,029        |
| Total, . . . . .  | <hr/> 104,090 |

*Animals Condemned.*

|                             | Number. | Weight. |
|-----------------------------|---------|---------|
|                             |         | Pounds. |
| Cows, . . . . .             | 29      | 12,437  |
| Steers, . . . . .           | 4       | 3,140   |
| Bulls, . . . . .            | 2       | 1,700   |
| Calves, . . . . .           | 6       | 270     |
| Sheep, . . . . .            | 3       | 130     |
| Parts of animals, . . . . . | —       | 2,500   |
| Total, . . . . .            | 44      | 20,177  |

*Tuberculosis.*

Fifty cases of tuberculosis were detected among adult cattle.

The following table shows the percentage of tuberculosis among cattle killed with the intention of being used for food : —

| CLASS OF ANIMALS.                              | Number<br>Received. | Tuberculosis. | Percentage. |
|------------------------------------------------|---------------------|---------------|-------------|
| Whole number of all kinds, . . . . .           | 34,521              | 50            | 0.14        |
| Cows from eastern states, . . . . .            | 2,014               | 44            | 2.18        |
| Cows from western states, . . . . .            | —                   | 3             | —           |
| Cows known to be from Massachusetts, . . . . . | 1,350               | 39            | 2.88        |
| Steers from western states, . . . . .          | —                   | —             | —           |
| Oxen from eastern states, . . . . .            | —                   | 2             | —           |
| Bulls, . . . . .                               | —                   | 1             | —           |

*Inspection of Cattle.*

The work of inspection of cows, as provided for by the Board of Health, and subsequently made compulsory upon cattle in general by an act of the legislature, has been continued during the past year. There are within the city limits about 2,400 cattle, distributed in about 690 barns ; all of these have been visited and the cattle in each, whether new or old, have been examined. Of the above-mentioned animals, seven have been pronounced suspicious, and the State Board of Cattle Commissioners notified that the same had been isolated. In making the above examinations, cattle have been found existing in all conditions and places. There are within the city limits people keeping a few cows, from two upward, who have not the

slightest idea of cleanliness, and practise little or none in the production of milk. Unfortunately a great many of such people are dependent on the sale of milk for a livelihood.

#### BRADFORD.

One case of tuberculosis has been reported, which was at once sent to the Cattle Commissioners, and the cow isolated as required by them and was, after examination by them, ordered to be killed.

The following regulation was drawn up and accepted by the Board and posted by them in accordance with the Public Statutes.

Regulation 40: No person shall keep swine or goats within the compact part of the town without a license from the Board of Health; and no swine shall be kept within three rods of any dwelling elsewhere.

There have been seventy houses where new plumbing has been done, and the inspector has thoroughly examined and accepted the same.

It is our advice that the town employ responsible parties, who shall, at stated intervals, collect the ashes and take charge of the dumping places, and that a contract be made with some responsible party to collect the swill and garbage as often as twice a week.

#### BRAINTREE.

By provision of law in towns not having a Board of Health, the selectmen act as such, having all the authority bestowed upon such Board. As the town is becoming more densely populated, stricter attention should be paid to the sanitary conditions.

We believe that the carrying of curtains or canopies from house to house as is sometimes the custom of funeral undertakers is a frequent source of contagion, and the practice should be discountenanced.

#### BROCKTON.

The following is a list of the principal complaints and nuisances investigated during the year:—

|                                 |     |
|---------------------------------|-----|
| Defective cess-pools, . . . . . | 102 |
| Defective vaults, . . . . .     | 65  |
| Filthy yards, . . . . .         | 115 |
| Houses placarded, . . . . .     | 126 |

The number of loads of cess-pool matter removed by the excavator wagons the past year was 12,210; the number of loads of night-soil removed was 3,099; the number of loads of ashes removed was 5,444.

The Sewerage Commissioners have completed the part of the work laid out for the year 1893, and, if as successful in carrying out their plans for sewerage the streets, will be able to take care of the sewage of the business part of the city the coming year.

A requisition was made upon the Civil Service Board of Examiners for a list of plumbers qualified for the position of inspector of plumbing. The names of three persons qualified to fill the position were certified to this Board, and one was selected and appointed by the Board as inspector of plumbing.

#### BROOKLINE.

The number of deaths reported from tuberculosis during the year (thirty, or over 12.5 per cent. of all the deaths, occurring principally as consumption), shows the need on the part of the public of a clearer understanding of the preventable nature of this too common disease. It may not be out of place to emphasize the fact that pulmonary tuberculosis (consumption) is absolutely proven to be a communicable disease, and quite easily communicated when the person exposed to it has his vitality depressed by such influences as foul air, indoor occupation, food poor in quality or insufficient in quality, bad ventilation, certain climatic conditions and especially fatigue from nursing a consumptive.

In April, the following order was passed : —

*Ordered*, That in case of death, when the deceased has not been attended by a physician, the certificate of death shall be issued by the Medical Examiner.

The public swimming-bath on Boylston street was open as usual during June, July, August and September. Early in the season the portion of the brook above the bath-house was inspected and cleaned out, and measures were taken to prevent pollution of the stream. Some necessary repairs were made on the bath-house to enable it to be used a little longer. Supt. Dillon reports that during the season 9,790 baths were taken, an increase of 2,101 over the previous year. Neither accidents nor illness have been reported, and many boys have learned to swim.

The importance, as a health measure, of frequent bathing in hot weather, and the great value of a public swimming-bath, both as a means of physical culture and of acquiring an art the possession of which saves many lives, can hardly be overestimated. The recommendation made last year by the committee on the bath-house is renewed, namely, that a more commodious swimming-bath be constructed.

The occasional need of a suitable building, owned by the town, for persons taken ill with diphtheria, scarlet fever or other dangerous contagious diseases (except small-pox) and having no home here, has received careful attention and it was

*Voted*, That in the opinion of the Board, it is necessary to erect a separate building upon land owned by the town, adjacent to the almshouse, for the care and treatment of patients with contagious diseases.

The emergency hospital for cases of small-pox, built by the Board in 1885, and fortunately never needed until 1893, was put in condition for patients, and, most important of all, ample facilities were provided for free vaccination.

Of the nine hundred and seventy-five persons who received free vaccination between December 1 and January 31, a very large proportion were natives of the British Provinces and never previously vaccinated. A number of alleged cases of small-pox, and of persons reliably reported as recently exposed to that disease, were promptly but quietly investigated by the Board, and all necessary precautions were taken in each case.

#### CAMBRIDGE.

Complaints and nuisances investigated during the year : —

|                                                             |        |
|-------------------------------------------------------------|--------|
| Full, overflowing and offensive privy vaults, . . . . .     | 733    |
| Offensive and defective water-closets, . . . . .            | 28     |
| Defective drainage, open and broken drains, etc., . . . . . | 61     |

The various dumps throughout the city have caused considerable annoyance and given rise to many complaints during the year. With a view to a more thorough control of the persons using these dumps and for the prevention of the deposit of improper material on them, the Board decided to employ a mounted police officer for as long a time as the appropriation at their disposal would permit. The short experience the Board has had with this means of prevention, has convinced it of its value.

Owing to the occurrence of some cases of small-pox in neighboring places, the Board decided to open three stations for free vaccination. Following is a list of vaccinations done up to the close of the year : — Station One, seventy-one ; Station Two, two hundred and four ; Station Three, one hundred and fourteen.

An unusual prevalence of scarlet fever, or of diphtheria, always raises a question of the expediency of closing the public schools. Setting aside the fact that Boards of Health have not this power, it does not appear as if such a proceeding would answer any useful purpose in the majority of cases in such a city as Cambridge. Any plan calculated to control effectively the spread of such diseases as scarlet fever and diphtheria must include the following measures : —

1. *Isolation.* Hospital accommodation will be required for those cases which cannot be properly isolated at home.

2. *Disinfection.* Carpets, bedding, clothing and such like articles can be disinfected by steam. This requires a proper plant.

3. Articles of little value that have been exposed to contamination should be burned.

4. The floor and woodwork of rooms should be well scrubbed with soap and hot water. Walls, ceilings, chairs, bedsteads and such other pieces of furniture should be thoroughly wiped with damp cloths, and the cloths burned.

5. Windows should be left open for several days. Fresh air and sunlight are among the most effective of purifiers

Burning sulphur, or the evolution of chlorine fumes, is a useful adjunct, but they cannot take the place of the measures mentioned above, and to rely on them is, in our opinion, a grave mistake. Disinfection means a process by which disease-producing micro-organisms are killed. It does not mean deodorization, nor does it mean the substitution of one smell for another smell. It is one thing to kill germs in a test tube; to do this in a room with all its cracks and corners and its unavoidable leakage is a very different business.

The mortality per 1,000 living, at all ages, was 19.72.

#### CHELSEA.

Under the act of 1890, which was accepted by the city council, three hundred and sixty-eight privies have been abolished this year, and the work will be continued the coming year, where, in the judgment of the Board, it is necessary.

Owing to the breaking out of small-pox in Boston it was thought best, as a precaution, to advertise free vaccination, which began the twentieth of December.

#### CONCORD.

It was thought best by the Board, after careful consideration, to stop all direct drainage into the river in this town.

Regulations were made by the Board relative to school attendance in time of prevalence of infectious diseases.

There have been two cases of glanders in this town the past year. In both of these cases the horses have been killed as soon as a positive diagnosis was given by the attending veterinary.

We make the following recommendations, and hope the town will take action on the same:—

That a system of sewage disposal of some kind other than the present be put in at once.

That some suitable piece of land be bought by the town to be used by the inhabitants of this town as a dump. Some place should be procured

far enough away from the centre of the town, off from the main roads, to which every one should cart his rubbish, ashes, tin cans, etc. No garbage of any kind should be allowed to be dumped there, and the place should be burned over once or twice a year. The places now used are unsightly, if not dangerous to public health.

That the board of health of this town consist of three members, one of whom to be elected annually, to serve three years, to be separate and distinct from the selectmen.

#### COTTAGE CITY.

During last August our attention was called to the condition of the waters of Lake Anthony. On investigation we found the opening through the beach to the sea nearly closed, and the water becoming stagnant had allowed the sea-grass and moss to grow in large quantity. Although not unhealthy, it has an unpleasant odor, and renders unsightly what is otherwise a beautiful sheet of water. We recommend the appropriation of a sum not exceeding one hundred dollars for the purpose of cleaning the shore of the lake and maintaining a sufficient opening to the sea.

To conform to the requirements of chapter 195 of the Acts and Resolves of the year 1892 we appointed an inspector of provisions and of animals intended for slaughter or kept for the production of milk.

#### DEDHAM.

There has been a great increase in the scarlet fever cases over previous years. Considerable care has been taken by the Board to prevent the spread of this disease, and the scattered and wide range of the cases rendered it practically impossible for the Board to anticipate results. Many of the cases were traced by the attending physician to outside sources, and beyond the control of the Board. It has been found almost impossible, in some cases, to make the parents understand the value of implicitly following the instructions given by the attending physician, and in one case it became necessary to enforce directions by means of an officer. The three deaths were all in one family where the cases were severest.

The reporting of the cases of measles has heretofore not been insisted upon. The value of such a report is chiefly for the use of the superintendent of schools in relation to attendance of pupils afflicted or exposed to this disease.

A large proportion of the complaints made to the Board during the previous year were from the keeping of swine in the more thickly-settled portion of the village. It was found difficult to allow the keeping of swine in certain localities without their being a nuisance. In consequence the Board adopted the regulations now in force, prohibiting the keeping of swine within the more settled portions of the village, with the result that the complaints and nuisances from this source ceased. Under the present

idea that swine must be kept in filth and mire the Board believes that the prohibition of their keeping in the closely-settled portions of the town is the only method whereby this nuisance can be disposed of satisfactorily.

The town must, at a very early date, take the question of sewerage seriously under consideration. Each year the demand grows more imperative. It needs but the inspection of a majority of cess-pools in this town to convince one of the necessity of a more sanitary and efficient method. The cost of caring for these unsightly and unsanitary receptacles is as great, if not greater, than would be the expense to the town of an efficient sewerage system. Many cess-pools are becoming choked up, and are merely cisterns to be cleaned out often at great expense and discomfort, or else allowed to overflow as a continual menace to health. It is earnestly hoped that the town will take immediate action in relation to the sewerage question.

In accordance with chapter 477 of the Acts of 1893 the Board has prepared a set of by-laws for the consideration of the town in relation to the regulation of plumbing and plumbers.

A matter of considerable importance has been brought before the Board this year in relation to the better drainage of Wigwam meadows and Little Wigwam swamp. This subject has been before the town for many years, and has been reported on by previous boards of health and committees. While such reports have been unanimously in favor of improving this drainage, little has been done in this direction except to clear a ditch from Wigwam pond to the river. After a hearing and careful examination of the locality in company with some of the petitioners the Board decided that a careful survey and thorough examination of the swamps and facilities for better drainage should be made as a guide for a proper consideration of the subject. In accordance with this, plans and a report with estimates have been prepared which treat the whole matter in an exhaustive and thorough manner. This report is annexed to the report of the Board.

#### EAST BRIDGEWATER.

The Board has visited several scarlet fever cases this year, and has seen to it that no persons passed in and out of the houses where such cases existed, except those who were absolutely obliged to do so. We have, also, visited several horses, and have condemned one as affected with glanders and ordered him disposed of. We have also examined and quarantined several tuberculous cattle, and shall see that they are also properly disposed of before their milk and flesh have infected healthy human beings. The Board has also corrected several extreme nuisances.

#### EASTHAMPTON.

There have been comparatively few complaints of the existence of nuisances as compared with former years. People generally evince a readi-

ness to comply with the requirements of the Board, and seem to more generally realize that it is for their own benefit to keep their premises in a neat and cleanly manner.

With the contemplated and partially constructed sewer system and the introduction of an abundance of pure water into more general use we are confident that the appearance of contagious diseases will be greatly lessened.

#### EVERETT.

The city has been remarkably free from summer diseases of children. There was an increase in the number of cases of some of the zymotic diseases. Cards have been put on the houses wherever there was a case of diphtheria or scarlet fever, and notice sent to the school committee, public library and State Board of Health.

Everett is a city of new houses. It will be a matter of a great deal of public importance to learn how many persons become sick with consumption while living in these new dwellings, or, in case of death from that disease, to learn if the person was afflicted before coming here. The Board has taken steps to obtain, as far as possible, and record these facts.

The Board has fumigated houses after contagious diseases when requested to do so. As the disinfecting done by householders is, in most cases, worse than useless, since it is often thought that the burning of one or two ounces of sulphur has destroyed all germs and no further precautions are necessary, the Board voted that, beginning with Jan. 1, 1894, all houses where contagious diseases had occurred should be disinfected by, or under, the personal direction of the Board or its agent.

#### FALL RIVER.

It is especially gratifying to note that the exceptional decrease in typhoid fever cases observed in the returns for the year 1892 has been maintained during the year 1893. The sanitary education of our citizens is undoubtedly making great improvement. The limitation of the spread of contagious diseases has been helped very much by the fact that early in the year this Board adopted the system of immediately placarding every house in which a case of scarlet fever or diphtheria was reported to exist, and ordering that the cards remain in place until two weeks after the recovery, removal or death of such patient or patients. We would recommend that, even though we have no reason to be apprehensive of a cholera visitation, a house-to-house inspection every spring would result in a benefit to the public health, fully justifying the necessary outlay. It is our opinion that provision should at once be made for an annual visitation of this kind. We know that such a yearly stirring up and cleaning of the city is absolutely necessary. Experience has taught us that it is only by such system-

atic inspections, the sources of all nuisances can be successfully located and the city kept in a thorough sanitary condition.

|                                                                                         |       |
|-----------------------------------------------------------------------------------------|-------|
| Number of live cattle examined, . . . . .                                               | 1,325 |
| Number of live cattle examined and reported as unfit for food or food supply, . . . . . | 6     |
| Number of meat carcasses examined, . . . . .                                            | 26    |
| Number of meat carcasses examined and destroyed, . . . . .                              | 15    |

The following is a summary of the work accomplished in the office of the Inspector of Plumbing during the year just ended : —

|                                      |       |
|--------------------------------------|-------|
| Number of plans filed, . . . . .     | 471   |
| Number of new houses, . . . . .      | 268   |
| Number of reconstructions, . . . . . | 203   |
| Number of approvals, . . . . .       | 425   |
| Number of inspections, . . . . .     | 1,899 |

#### FITCHBURG.

During the past year the city has been visited with one of the most extensive epidemics of measles in its history, there being 592 cases reported to the Board. The disease was not of a severe form, and the number reported did not express the total number of cases. It began in January and rapidly increased until May, when 270 cases were reported. It as rapidly declined during the summer, and in August only one case was reported.

In regard to diphtheria the number of cases was ten, and was below the average for the past four years, during which time the records have been carefully kept, the average being 14.5 for the period. The cases showed a milder form than usual, there being only three deaths, one of which was called croup. The largest number of cases occurred in the first three months of the year, conforming to the average for four years.

There were twenty-eight cases of scarlet fever reported, as compared with fifty-one for 1892, and an average of sixty cases for the four-year period. The cases were unusually light, no deaths from the disease being recorded. The largest number of cases reported was in June. This does not conform to the average for four years, during which time the largest number of cases have been reported during the first months of the year, February showing the largest number of any single month.

During the year just past there have been twenty-three cases of typhoid fever reported, the largest number for four years, and six more than in 1892, when seventeen cases were reported. There were four deaths reported as compared with none for 1892. The largest number of cases occurred in September. A comparison of the records for the four years

past shows but few cases occurring during the first six months of the year, July, September, October and November showing the largest number.

The house-offal teams have been continued in the work of collecting swill as in the previous four years, doing good work in promoting cleanliness of the city. During the past year 363 cords of house offal have been collected and carried to the place of deposit.

The rules relating to plumbing have been carefully revised to keep pace with the science of plumbing and house drainage. The result of the work of the Board for the past year shows a vast improvement in the quality of plumbing work, and still better results are hoped for the coming year.

|                                                  |     |
|--------------------------------------------------|-----|
| Complaints received, . . . . .                   | 272 |
| Privy vaults discontinued, . . . . .             | 114 |
| Plumbing jobs inspected, . . . . .               | 362 |
| New water-closets inspected, . . . . .           | 513 |
| Houses fumigated or instruction given, . . . . . | 181 |

#### FRAMINGHAM.

Fifty-five complaints of existing nuisances have been made to the Board during the past year, all of which have been attended to and abated as far as was thought best. The owners of fifty-three tenements have been ordered to connect them with the public sewer.

#### GARDNER.

Realizing the great importance of milk as an article of food, early during the past season we requested the co-operation of some of our neighboring towns in a closer inspection of the milk that was being delivered in this town; failing in this, we would recommend that no person be granted a license to sell milk in Gardner unless such person furnish an acceptable certificate of cattle inspection.

The work of the cattle inspectors during the year has added much toward the improvement of the milk. They examined thirty-three herds, three herds more than last year. Some cows were examined five times. The inspectors condemned and caused to be killed eight cows, and condemned four carcasses. At the present time all the cows in town are considered in very good condition.

We would earnestly recommend to every family who depend on wells for their supply, or for the supply of their cattle, to use the greatest possible care of their wells, and avoid all possible contamination from cesspools, water-closets and barns, or other filthy matter. By doing so they will in a great measure protect themselves from typhoid fever.

We have to report quite an extensive epidemic of typhoid fever, but rather mild in its character, and fortunately resulting in only one death. We believe that had the Board known earlier the existing circumstances this epidemic might have been somewhat lessened. As soon as the Board

investigated and found the source of infection the epidemic was confined to a very small radius, and soon brought under control. It resulted from impure milk occasioned by impure water.

#### GLOUCESTER.

One hundred and ninety-three nuisances received attention. All *bona fide* nuisances have been abated where possible, but in a city without sewerage it is occasionally advisable to be very lenient, especially where some neighboring quarrel seems to have been the animus of the complaint, which sometimes appears to be the case.

If sewerage is not soon adopted the city must resort to some method less objectionable than the present method of disposing of night-soil and sink-waste.

#### GREAT BARRINGTON.

During the year the selectmen, acting as a board of health, have been notified of twenty-seven cases of scarlet-fever, of which but one proved fatal; and four cases of diphtheria, of which number two cases proved fatal. The board adopted the usual sanitary measures of precaution in such cases. We believe that the cause of many of these cases exists in the carelessness on the part of individual families in the disposal of garbage and neglect to keep the dwellings properly cleaned. Dirt and refuse matter are two great enemies to public health, and we cannot urge too strongly the importance of an observation of the utmost care in these measures.

#### GREENFIELD.

The Board feels that the most important matter they have to recommend to the careful consideration of the town is the subject of sewers. This is a very broad subject and difficult and impossible for us to treat in the thorough manner that it demands. Our present system, if system it can be called, is totally inadequate for the needs of our growing town; many sections are entirely unprovided for, and many other sections where there already is a public sewer, suffer great expense and inconvenience at the time of a heavy rainfall, owing to the inability of the tile to carry off the large amount of surface water that is thrown into it, and in consequence cellars are flooded. This difficulty is experienced more or less throughout the whole town and sooner or later the surface water will have to be taken care of in some other way.

#### HAVERHILL.

The appointment of an inspector of plumbing has been a great relief to the agent, and great public good will be the outcome, for, as we have already stated in previous reports, it is found impossible for the agent, in addition to his other duties, to give this branch of the sanitary service, so extremely important, the attention and careful supervision that it should have. Plumbers are now required to test their work by water pressure in

the presence of the inspector, which gives a much more thorough and satisfactory inspection. The record shows that three hundred jobs of plumbing (new and remodelled) have been inspected last year.

*Nuisances Investigated During the Year.*

|                                                            |       |
|------------------------------------------------------------|-------|
| Garbage collected, loads, . . . . .                        | 1,320 |
| House sewerage defective, . . . . .                        | 42    |
| Plumbing defective, . . . . .                              | 30    |
| Privy-vaults full and offensive, . . . . .                 | 138   |
| Privy-vaults cleaned, . . . . .                            | 300   |
| Privy-vaults removed, . . . . .                            | 142   |
| Whole number of privy-vaults removed since 1888, . . . . . | 1,002 |

The general health of the city during the year has been excellent. No fatal epidemic has visited the city.

The faithfulness and care with which contagious diseases are reported by physicians speak well for the interest in their profession and in the public welfare. Notwithstanding the wide publicity that has been given to the law that requires householders as well as physicians to report dangerous contagious diseases to the Board of Health, some cases occur where the disease is so mild that the children are hardly considered ill enough to be put to bed, and consequently no physician is called and no report comes to the Board. Thus no efforts are made to prevent its spread, and great damage is liable to be done in consequence by spreading the disease in the neighborhood in a malignant form.

HINGHAM.

Early in August, complaints having reached the Board regarding a tallow factory at Fort Hill, representatives of the Board visited the establishment, which they found in a filthy condition.

The business seemed necessarily to give rise to offensive odors, and although the health of the community should always be paramount to the pecuniary interest of any individual or firm, at the earnest request of the proprietor a further time was granted on the plea that the business had but recently been established and the firm had been unable to put their manufactory into proper shape. The claim was also made by the proprietors that they, by undergoing a larger expense, could use apparatus by which all offensive odors would be destroyed. They promised to introduce such machinery at once, and an opportunity was given them to make such changes.

The establishment was several times visited by members of the Board, to watch the results of any changes made by the proprietors. On September 22, no better results having been obtained, the business was declared a nuisance by this Board, and they were ordered to close their works at once, which order was promptly obeyed.

## HOLYOKE.

The past year throughout the city has been fairly healthy. None of the contagious diseases have prevailed at any time to an alarming extent. Although there were numerous cases of diphtheria and scarlet fever during the first four months of the municipal year just ended the number of cases during the rest of the year and at present is much below the average.

Small-pox again appeared in our midst during the month of September. Although limited to a single block, it attacked three persons, all of whom recovered after a more or less protracted stay at the pest-house. Here again the city physician desires to call your attention to, and to emphasize a recommendation of the Board of Health, viz., that there be a general vaccination. The Board of Health calls your attention to a deficiency in the heating apparatus at the pest-house. That such a deficiency exists was only too apparent during the stay of the recent cases, and, added to this, was a failure in the water supply. The water at the pest-house, obtained from a well sunk beneath the kitchen, has always been of a very poor quality, but this year it became so impure it had to be discarded even for washing purposes.

We have been remarkably free from typhoid fever during the entire year.

The Board this year as heretofore recommends that all the alleys be graded, and that those between our principal business streets, through which heavy truck-teams pass, be paved with stone, brick or any other material which seems proper.

## HUDSON.

The greatly increased number of calls to look after nuisances caused by the disposal of waste water, has convinced the Board that the time has come when the town ought to take initial action with regard to a system of sewerage. When all the water used by consumers is pumped or drawn from wells, the quantity used may be easily disposed of in cesspools, and taken care of by the surrounding earth without danger of infection, if the cesspools are emptied and cleaned periodically. Or, if the waste water is discharged into natural waterways, it may cause no nuisance in a sparsely settled locality, or if there are only a few discharge pipes. But, when an abundant supply is furnished by the town water-works, and its use is almost universal, the quantity used is so much increased, that it is only a question of time when the earth about cesspools will become saturated with water, and entirely filled with decomposing filth. And this condition will be found, not only on one man's premises, but in entire neighborhoods, growing worse constantly as they become more thickly settled.

The Board would recommend the voters to take action by appointing a committee to consider the question of a sewerage system, with authority to

consult the State Board of Health and obtain their advice and instructions, and with authority to employ a competent civil engineer to make surveys, plans and estimates for a complete system of sewerage, and take any action necessary to make a full report to the town on the subject at some subsequent meeting.

#### IPSWICH.

In regard to the sanitary condition of the town, the people, generally, have complied with the requirements of the Board, and in no case where we have ordered a nuisance abated have we had any trouble or had to resort to legal measures.

In regard to contagious diseases amongst the cattle in the town we will state the following: the selectmen appointed a cattle inspector, and the Board of Health also appointed him as their agent giving him full power to act for them, and he has faithfully attended to his duties. The whole number of cattle inspected by him was eleven hundred and four, and he ordered nineteen of this number quarantined as, in his opinion, they were diseased, and notified this Board of his doings. The State Cattle Commissioners were at once notified in regard to same, who came and examined them and ordered the killing of eight which were sick with tuberculosis, and their carcasses were properly buried.

#### LAWRENCE.

Six hundred and seventy-four vaults have been abolished since Jan. 1, 1889. There have been 2,184 water-closets placed in buildings where vaults have been abolished.

During the year 19,714 loads of garbage have been removed, an increase of 4,376 over 1892. Realizing the necessity of a different method of disposing of the waste matter, the Board has recommended that some provision be made to dispose of this material in a satisfactory manner.

There has been an alarming prevalence of scarlet fever during the year, and the percentage of fatalities greater than formerly.

More cases of measles have been reported than ever before, forty-six cases coming in during one week. The fatalities have been small, only three out of sixty cases resulting fatally. Diphtheria has not been very prevalent. During the December vacation, 3,200 school children were vaccinated by the ward physicians. We were pleased at the ready response from the agents of the corporations as we found that vaccination was being carried on in a very systematic manner.

We have had five cases of glanders in horses and seven cases of tuberculosis in cattle, which were pronounced such by the Cattle Commissioners.

#### LEXINGTON.

The Board has made several official tours of inspection; among them *was* the inspection of the several hotels and private boarding-houses, and

we are pleased to state that, with few exceptions, the sanitary conditions were good. The inspection of some of the numerous newly built houses was not so assuring; indeed, the systems of house drainage in many of them were alarming. One case, for instance, may be cited: a double tenement; no water supply except from well dangerously near drain; untrapped sinks discharging into an open tank in cellar, contents of which were used to flush closet; without vent; useless trap; cesspool twenty-eight feet from house. It would almost seem that the ingenuity here displayed tended only toward one result, — the death of the occupants.

Some years ago the question of a sewerage system for the town was agitated to the extent of the appointment of a committee, the investigation of different schemes was initiated, and even the engineer's survey obtained. This subject, so vital to the interests of the town, seems to have passed into oblivion; nothing is heard of it except now and then a few desultory remarks on the matter. It is hoped that this subject is not entirely forgotten, for if forgotten and neglected there will be a rude awakening, perhaps within a few years.

#### LOWELL.

During the year 1893, twenty-five thousand five hundred and thirty-seven (25,537) loads of ashes were removed from houses and stores to the various dumping-grounds.

Late in the year 1892, the Engle cremator was completed so that for the year covered by this report it has been in use, destroying about one-half of the garbage of the city. Owing to the usual friction that all new undertakings have to overcome, it was not until April that a complete system of account was commenced. Since April every pound of swill consumed and every pound of coal used has been weighed daily so that, estimating the amount burned the first three months of the year and adding to it the amount weighed for the last nine months, we have, say 3,500 tons of swill consumed for the year 1893, beside the miscellaneous articles enumerated in the table printed herewith:—

Three thousand five hundred tons swill and market refuse burned.

Four horses.

Seventy cats.

Sixty-three dogs.

Two hundred and fifteen mattresses.

Four hens.

Seven rabbits.

One raccoon.

Three loads and one barrel infected clothing (small-pox).

Seven loads infected clothing (diphtheria).

Seventy-seven thousand one hundred and sixteen pounds paper burned on ground in rear of cremator.

The opinion of the Board, after the experience of the year with the Engle cremator is briefly this: Under no circumstances would it be willing to return to the old method of swill-house distribution to farmers, and it is also convinced that cremation of the garbage is more satisfactory to the inhabitants of a city than the rendering process. The cost of burning garbage at Engle cremator, from Jan. 1, 1893 to Dec. 31, 1893, was \$7,670.77.

The Board caused a thorough inspection of the water-shed of River Meadow brook to be made, and the results are such as to demand prompt remedial and preventive action.

The work of inspecting the tenement houses of Lowell in a thorough and systematic way has been commenced this year, and so far the results have been very satisfactory; but the great value of the inspection will come in later years, as from the records made and kept by the library system, an inspector can turn to them at any time and find the condition of any house in the city so far as relates to plumbing, drainage and ventilation, and will then only have to keep watch that the premises are kept clean and in repair.

From June 27 to September 16, there were 14,918 baths taken by men and boys, a decrease from 1892 of 8,347, but it is explained by the fact that more than that number used the house to put their clothes in, and then came outside and swam in the river.

#### LYNN.

The Board of Health appointed an inspector of plumbing under the provisions of chapter 477, Acts of 1893.

Under the provisions of a special act of May 4, 1893, chapter 313 (1893), the Board of Health of Lynn was authorized to appoint an "inspector of provisions, and of animals intended for slaughter or kept for the production of milk, who should also be an inspector of milk, butter, cheese and vinegar."

Each of the officials appointed under these acts contributes a full report of his transactions.

The Board recommends the following amendments to the milk laws:—

1. That the cost of analysis be charged as court costs.
2. That boards of health be vested with power to revoke licenses.

The failure of the city government to carry out our recommendations or to adopt a system for the disposal of garbage and night-soil placed the Board in the predicament, on April 20, of having no place to dump that material, or otherwise dispose of the same by cremation or extraction. To relieve the situation the city purchased the land about the outfall sewer, and we entered into contract with an excavating company and had a temporary basin dredged for the scow on land alongside the outfall sewer at West Lynn. A dock was also constructed with a small, frame building thereon. The disposition of offal by loading it into the scow, towing it

twelve miles out to sea and there dumping it in deep water, was inaugurated, and has proven a success.

Twelve trips have been made and 1,486 tons of offal so disposed of, without accident or a single complaint, at a cost of ninety-four cents per ton for labor, towage and expense of repairs. We shall pursue this method until the city council adopts some other and better one. We recommend the immediate purchase of another scow. The dump at West Lynn was abandoned on the expiration of the lease, April 20, and no garbage was placed thereon after that date.

The Board requested that immediate steps be taken by the city council to provide suitable accommodations for persons affected with contagious diseases.

#### MARBLEHEAD.

The health cart is one of the most important institutions in our town, and we hope has come to stay both summer and winter. Two thousand loads of refuse matter have been collected the past year. To find persons who will look after this refuse and see that it is properly covered has caused the Board considerable trouble. We suggest that the town set aside a place to be used as a dump in case there were no individuals who cared to take it.

We suggest that our town should employ a health officer to investigate nuisances, post notices, inspect meat, milk and water, attend to the fumigating of all places where infection exists, and who would be in many ways of great service and value.

#### MARLBOROUGH.

In parts of our city where the health of our citizens was in danger, and along the banks of brooks, during the past two years, this Board through its agent has enforced connections with the public sewer under the powers granted in the Public Statutes, chapter 132 of the Acts of 1890. The agent of the Board reports that two hundred and sixty-seven buildings have been plumbed; one hundred and fifty-one cases where alterations or additions have been made in the plumbing; making a total of four hundred and eighteen inspected and approved by him. It is evident from the number of inspections made that the people are mindful of the economic and sanitary advantages of the public sewer. The enforcement of our regulations governing plumbing worked to the advantage of all.

Many nuisances that have been a bugbear to every Board of Health for years past have disappeared entirely since the house drainage in these localities has been conducted to the sewer. Cards calling attention to the regulation restraining persons from making the vacant land of the city a nuisance, were posted wherever there seemed to be a cause of complaint.

In August a case of rabies appeared in town. A dog with a disease of doubtful diagnosis was killed by the police. The mayor with a representa-

tive of the Board of Health agreed to request Dr. Ernst of the Harvard Medical School to decide by inoculation experiment whether the disease of the supposed mad dog was actually hydrophobia. The result of the experiments proved that the dog was afflicted with the genuine disease, and proved the wisdom of muzzling all the city dogs. No more cases appeared though several dogs were said to have been bitten by the diseased dog.

#### MAYNARD.

The Board has encountered a greater obstacle in trying to educate a certain class of people to understand that it is necessary to flag a house where there is scarlet fever and cause the flag to remain displayed for a proper and legal length of time. They also have seemed to think they were doing the Board a great favor by allowing the flag to be attached to the house at all, and as soon as the case is able to sit up, "although then probably in the most contagious stage," display more or less disposition to resent the idea that it is then highly necessary that the quarantine should remain longer. This condition can only be overcome by education.

#### MEDFORD.

Sixty-one nuisances have been reported to this Board during the year. All have been carefully investigated and abated.

In each case of diphtheria, measles, scarlet fever and typhoid fever, the clerk has notified the school committee and librarian of the public library.

The work on our local sewage system should be pushed to completion as rapidly as possible, so that we may be rid of that increasing and menacing danger, the saturation of the ground with sewage. Since the collection of ashes, swill and garbage has been under the direct care of the city, and the contract system abolished, the work has been done in a thorough, cleanly and efficient manner, and the results are highly satisfactory to this Board. With the same arguments we have used in the past, in favor of the collection by the city of ashes and swill, we would now earnestly recommend that night-soil be collected in the same manner.

#### MELROSE.

More than one hundred and fifty nuisances and complaints have received attention from the Board. The sources of nuisance or complaint have most frequently been neglected cesspools and offensive privies, but also imperfect traps, or total absence of them, and defective sink drains.

The former method of return to school by children recently recovered from contagious diseases, has been by permits given by the Board, based upon the attending physician's certificate of recovery. But that method having often proved troublesome to parents, a more direct plan is now employed, of permits, based as above, but issued by the chief of police, as

The subject of maintaining bath-houses all the year round was the subject of a special recommendation by His Honor the mayor in his inaugural address to the city council, and a special commission has since been appointed by him to consider the subject, and make such recommendations with a view to establishing such accommodations as may be deemed expedient. The supplying of public bathing facilities during the winter as well as during the summer months has the cordial approval of the board of health, as being in the line of promoting the public health.

#### *Examination of Plumbers.*

The examining board held 44 meetings and examined 258 candidates for plumbers' licenses; 93 were for master plumbers' licenses, and 50, or 52 per cent., passed the examination and were licensed; 165 were examined for journeymen plumbers' licenses, and 106, or 64 per cent., passed the oral examination and were notified to report at the shop for a practical test. Of the 106 candidates who passed the oral examinations, 77 passed successful examinations in the shop and were given licenses.

#### *Lying-in Hospitals.*

During the year 423 confinements have taken place in the licensed hospitals, and no deaths have been reported.

#### *Stables.*

There were 248 applications, and 198 were granted.

#### *Prosecutions.*

During the year there have been 30 prosecutions for violations of various health laws. In these cases there were 25 convictions, 2 acquittals, 2 were *nol-prossed* and 1 is still pending.

Of the convictions, perhaps the most important was that of a physician for failing to report a case of contagious disease which he had been called to attend. In this case a fine of fifty dollars was imposed in the lower court, and, after an appeal and trial before a jury, the judgment of the lower court was affirmed, and the fine increased to one hundred dollars.

The physicians of the board examined 39 cases reported as small-pox, none of which proved to be such.

The bodies of 454 persons dying without a physician were also examined, to determine the causes of death.

#### *Animals killed at Abattoir.*

|                   |        |
|-------------------|--------|
| Cattle, . . . . . | 25,814 |
| Calves, . . . . . | 14,141 |
| Sheep, . . . . .  | 77,906 |
| Swine, . . . . .  | 470    |

The cases of scarlet fever were also widely separated as to families affected, and there has not been a general epidemic, all the cases having occurred in but six different houses.

The occurrence of five cases of typhoid fever on one street and within a short radius would seem to imply some local contamination, but no obtainable evidence could satisfactorily explain the origin of the disease. Chemical examination of well waters furnished little light, but since the disease is generally believed to be of bacterial origin, it might well happen that a chemical analysis would give entirely negative results. The milk supply theory did not apply, since there was not a common supply in the different affected families, nor was any disease known on the premises from which the several supplies came. Without attempting to show any connection between the facts, it may be stated that fourteen of the cases were comparatively near the river, eight of them being very near. A very extensive epidemic of measles occurred in the autumn.

It is well for people everywhere to know that it is now believed by the highest medical authorities that consumption is to a very considerable degree communicable from person to person, and that the germs abound in matter expectorated in coughing; that constant care should be taken to disinfect and destroy such discharges, and especially that the common habit of promiscuous spitting should be avoided. Matters so scattered, by drying, become converted into dust, and, in this form, are widely scattered to be inhaled by others, and since the germs are extremely tenacious of life, the seeds of the dire disease are widely sown.

It cannot be doubted that such precautions as are above described would, if generally adopted everywhere, have a marked effect in diminishing the frequency of consumption.

During the year two cases of glanders in horses have been reported to the Board by the inspector of cattle. Both animals were subsequently condemned by the State Cattle Commissioners and killed by their order.

#### NANTUCKET.

The Board made investigation of many nuisances reported, and believes that the town has been kept in an improved sanitary condition in consequence of a general interest manifested by all good citizens, to live up to the best ideal of proper sanitary safeguards. As a result of such care and attention, no contagious disease of any kind has been reported to the Board during the year as originating at Nantucket.

#### NEEDHAM.

The health of our town and its freedom from any serious epidemic of infectious and contagious disease (except that of typhoid fever) during the past year is a matter of sincere congratulation.

What will soon be required as the town progresses, to put us in a

thorough sanitary condition, will be a general system of sewerage, which the introduction of a public water supply generally demands.

Your health officer has made one hundred visits of inspection and examination, visiting sixty places where complaints have been made. Fewer petty complaints have been made than in previous years.

Fewer swine have been kept in the thickly settled portions of the town than in former years. Some piggeries have been entirely abandoned. In a few cases, as a last resort, the Board appealed to the court to enforce its orders.

#### NEW BEDFORD.

The Board acting under authority of Public Statute, chapter 80, section 24, vacated houses on Turner's court known as Holy Acre. This act the Board regards as one of the most important taken during the year. The statute places the entire responsibility on the Board. The houses in question were so low that it was impossible to drain them, and it seems unfortunate that there are no means of preventing building or moving houses already built to such locations. In every growing city, building is continually outgrowing the drainage system. But for such buildings drainage can be supplied before they are occupied. The policy of the Board has been and will be to vacate all such tenements at the first sign they give of danger to the public health. The Board would recommend that action be taken on the proposed building rule establishing the height of cellar floors above high water. The nuisance caused by privies is being rapidly abated, when such a nuisance occurs on the line of a sewer.

All garbage is ploughed in daily, and when about one acre is covered a quickly growing crop is planted, and in a surprisingly short time, on digging down, no garbage can be found. Thus the essential condition for rapid decomposition in the earth is attained, namely, superficial burial. The objection to superficial burial is that the burial products may more readily become exposed and so cause nuisance, or, by drying, blow about, and under proper conditions cause disease. This objection is met by the facts that the material buried is not of such a character as frequently contains disease germs, and the moist and heavy condition of the soil is such that it is seldom dry except upon the surface. The farm is remote from any source of water supply. So far the method is satisfactory in all respects. The material is thus utilized as a fertilizer, which is its only value, as the cost of extracting the fat, the only constituent of value, would more than counterbalance the estimated return.

The Board voted to inspect the sanitary condition in respect to drainage of the various school houses in the city. All, with the exception of one, were found in good condition. The school committee were notified of the condition of this school.

|                                             |           |       |
|---------------------------------------------|-----------|-------|
| Number of inspections made during the year, | . . . . . | 2,384 |
| Number of plumbing inspections made, .      | . . . . . | 1,650 |

The Board investigated an epidemic of typhoid fever which occurred in the last half of the year, embracing 201 cases in all. No satisfactory conclusions were reached which would account for the epidemic as a whole, though suspicion pointed strongly to the existence of infection upon a small island in the harbor which many of the persons attacked had visited during the period of epidemic.

The Board amended its quarantine regulations and publishes them in full in its report.

#### NEWBURYPORT.

There has been a great falling off of cases of diphtheria and scarlet fever from the previous year, but a large increase of cases of typhoid fever.

Rules and regulations relating to plumbing were adopted by the Board.

#### NEWTON.

The general health of the city has been good, and barring slight outbreaks of diphtheria in the early spring and fall, and an epidemic of measles in the early summer, would have been deemed excellent.

The contagious wards at the hospital have been found very useful during the year; the early removal of patients to them having greatly aided the Board in preventing the spread of disease. The wards have been in almost continuous use during the year, sixty-two cases having been admitted. The cases were divided as follows,—scarlet fever, fifteen; diphtheria, twenty-eight; measles, nineteen.

The Board authorized free vaccination to all comers in the several villages.

#### NORTH ANDOVER.

As a matter relating to public health, we think the attention of consumers of milk should be called to the fact that most of the herds supplying milk in this town are not allowed any exercise at all, but are tied up by the neck from November till May in badly ventilated barns, and never turned out of doors.

We recommend the purchase of one of the odorless pumps, and that its use be made compulsory in the village whenever vaults or cesspools are cleaned during the day.

We find occasionally a person who is willing to allow his vault to overflow his neighbor's land. Such need the stimulating effect of the sharp end of the law.

#### NORTH ATTLEBOROUGH.

The failure of people to submit to the guidance of any fixed rules for observance in trying to prevent the spread of any infectious disease is often due to thoughtlessness rather than to a desire to thwart the beneficial effects of such rules. It often requires the experience of an epidemic to

teach the public that there are certain rules and regulations which must be strictly observed.

There has been a marked decrease in the number of cases of diseases of a contagious character reported during the past year.

#### ORANGE.

With the opening of the season the Board recognized the need of removal of "waste, filth and house dirt," and engaged a scavenger who gave two days each week to the collection of rubbish and garbage on the principal streets of the village during the heated season, with the result that never before in the history of Orange was the town in as sanitary a condition.

The Board has investigated one hundred sources of filth and offence. The members, individually, have investigated many others.

The Board of Health would urgently request parents to investigate the subject of "vaccination" thoroughly, that they may intelligently act regarding it.

The bodies of five dead animals have been buried by the Board. Animals infected with tuberculosis have been condemned. Herds have been inspected by the Board's agent. Horses with infectious diseases have been cared for, and dogs killed.

#### PITTSFIELD.

The sewage system, now almost completed, has furnished a long-needed want, and the amount of good obtained by the same is immeasurable.

During the year 1893 the new ordinance for plumbing necessitated the licensing of plumbers and drain-layers.

|                                                          |     |
|----------------------------------------------------------|-----|
| Number of licenses granted to plumbers, . . . . .        | 8   |
| " of licenses granted to drain-layers, . . . . .         | 13  |
| " of plans of plumbing submitted for approval, . . . . . | 253 |
| " approved, . . . . .                                    | 218 |
| " rejected, . . . . .                                    | 35  |

During the past year the Board of Health has been called on to investigate four outbreaks of tuberculosis at different farms. At one farm the Board considered about thirty per cent. of the cows affected. So far, twenty-one of them have been slaughtered, and of these nineteen have been found diseased, while two were found not diseased. At another farm over fifty per cent. were considered unsound. Up to date thirteen have been slaughtered, and every one has been found diseased. At another farm two cows have been slaughtered, both of which were affected. The Board considers that the chief cause of its spreading among dairy cows is overcrowding, deficient cubic air space and defective ventilation. The Board also considers a more thorough State system for regulating and managing the disease should be inaugurated.

## PLYMOUTH.

Sixty-three places have been examined and nuisances abated without having received any formal complaint.

Nearly all of the cases of scarlet fever, typhoid fever and diphtheria have been traced by the Board to imperfect drainage and ventilation.

After learning the facts in the cases the Board issued orders to those families from which cases were reported, and had them enforced; and the Board felt that after the last case was reported well, and the places had been disinfected, that there would be no danger from these sources. During this time circulars were distributed by the Board throughout the town giving instructions what to do in case of diphtheria.

In accordance with the Acts of 1893, chapter 477, the Board has appointed inspectors of plumbing, and, at the request of the selectmen, prepared a list of by-laws, and presented them to the town for adoption.

## QUINCY.

Your Board strongly recommends that plumbing regulations or ordinances be enacted by the council as a matter of safety to the public health. The inspector is powerless without them in many cases. The brooks have been thoroughly cleaned under the direction of the inspector, and the Board has every reason to believe that the work has been economically, thoroughly and conscientiously done. The physicians are negligent in their duty of reporting contagious diseases, and until they are brought up to the law the same state of affairs will exist.

Number of nuisances discovered, 306; number abated, 298.

## READING.

There have been twenty-one nuisances investigated, and all cases except two have been abated by owner or occupant. One of these was abated by the Board, and the owner paid the bill. The other one will be attended to before the premises are occupied.

## REVERE.

The town has been favored with a freedom from contagion to an extent to be a matter of satisfaction to the citizens within the last twelve months. Scarlet fever showed itself the latter part of the year. The prompt and stringent requirements of the Board have done much to prevent it being spread over the town.

## ROCKLAND.

We have had one case of glanders reported during the year, and the Cattle Commissioners ordered the horse killed, which was done.

One of the vital questions for the people of this town is that of sewage. While in our present financial condition, any general system for the town

to adopt would be too expensive, yet there is a very simple and effective way of disposing of sewage that could be adopted by individual families. The plan is to have the sewage pass through an underground drain with branches in all directions, the drains to be constructed of broken drain-pipe, stones or anything that will allow the sewage to pass into the ground at short intervals.

#### SALEM.

In the month of February a sharp outbreak of diphtheria occurred near the cotton mills. The type of the disease was very serious and vigorous measures were employed to combat it. Houses were guarded night and day by police officers, thus stopping one of the chief sources for spreading the disease. Everything possible was done for the sick and for the afflicted families.

Though some cases of scarlet fever were severe, only one proved fatal. The type has generally been mild. We note with satisfaction the marked decrease each year for the past three years in the number of cases of this dangerous malady.

The type of typhoid fever was severe and active search for the cause was made by this Board, milk being particularly looked after. Visits to each house were made, also to shops where milk was sold, and the milkmen, their farms, the cattle, the sources of water supply of the cattle. The fault could not be traced to the milk.

The work of collecting the ashes and rubbish the past two months has been done in a very satisfactory manner. Eight thousand one hundred and seventy-two loads have been collected. This is an increase of over 1,400 loads more than in 1892. These ashes have been used to fill up unsightly and often unhealthy places in our city.

#### SAUGUS.

The Board made personal investigation of a number of reported nuisances, and on their tour found much work to be done in regard to neglected privies and vaults. These cases were reported to the owners, and in the majority of cases were looked after in a satisfactory manner. Our inspector also found many places where sinks were not secured by traps, which allows of all gases arising from contents of cesspools to flow back into the rooms occupied by the residents. This should not be allowed, and the Board has obliged owners to correct these troubles so far as its knowledge of them is concerned.

Perfect cleanliness of dwellings and surroundings is what will insure good health and is of the utmost importance, as by its strict observance the air is not polluted and germs of disease find no lurking places.

The Board publishes a very full and complete set of regulations including practical instructions relative to disinfection.

the lake by the construction of a dam across the opening, by which means the water was changed from salt to fresh. We succeeded by this means in destroying the grass, as evidenced by the large quantities which came ashore during high winds, and the accumulation thus coming ashore was raked up and carted away as soon as possible.

#### DANVERS.

There was an epidemic of measles during the spring and summer, probably many more cases than were reported, as the disease is often so mild that no physician is called to attend.

The cases of diphtheria were treated with the new remedy, diphtheria antitoxin, of which so much has been expected. We have thought it advisable to keep an antitoxin syringe and a supply of antitoxin on hand, so that any physician in town can obtain them of the board of health at short notice.

The time is not far distant when the town must adopt a general sewage system, which is the only satisfactory way of disposing of the sewage in thickly settled parts of the town.

#### DEDHAM.

The town is to be congratulated, both in being able to obtain so excellent a service as will be hers when the metropolitan sewer is completed, and also in having the prospect of obtaining so speedy a relief from the extremely unsanitary conditions now prevailing in her midst. Upon the completion of the trunk sewer the town must construct a system of lateral or branch sewers to connect therewith, and some provision must be made for this purpose in the near future.

The keeping of swine in the town and the teaming of swill and offal through the streets seem to be an annual source of difficulty and nuisance.

#### EVERETT.

In July it came to the knowledge of the board that there were some unreported cases of diphtheria. The attending physician was prosecuted and fined fifty dollars in the district court. In these cases the probable source of infection was an old lounge that had been brought from out of town and upon which a child had died with diphtheria. It was put out in the yard, and the children had used it. Very soon there were 7 cases and 1 death in the neighborhood. Possibly there were other mild cases that were not recognized. There has been a number of cases since in that locality. In a number of instances we are quite sure that the disease has been contracted from infected persons from out of town or by children visiting infected houses in other places. In one case a child was sent here because its brothers had the disease. This child remained well, but a child in the

## WAKEFIELD.

We have had no epidemic. The general complaints of nuisances have been few and soon abated, and the more important ones have caused us little trouble. Our formal meetings have been few, but all that were necessary, as the members of the Board met almost daily and the business was often informally discussed and disposed of. We have done nothing toward abating our permanent nuisances this year, as we have concurred with the opinion of past Boards that the expense of the attempted improvement would far outweigh the very doubtful benefit. There is but one way to rid the town of these unsavory and unsightly spots, and that is by a proper sewerage system.

During the session of 1893 the Massachusetts Legislature passed a law governing the business of plumbing in cities and towns in the State. In accordance with this law we appointed a local board of examiners of plumbers.

## WALTHAM.

A request by the Boston Manufacturing Company to remove some cases from corporation tenements compelled the Board to make provision for the treatment and care of scarlet fever patients, and, at first, quarters were engaged in the Newton Cottage Hospital; but the number of cases increased so rapidly that the Board deemed it more convenient and economical to procure a house somewhere in the city for temporary use as a contagious hospital. The result was that the house No. 255 South Street was taken for that purpose, and a house-keeper and a nurse were procured to take charge of cases carried there. This house was maintained as a hospital from March 14 to May 15 and proved ample to accommodate all cases of children sick with scarlet fever whom it was desirable to remove. On one occasion, a mother and child were furnished with board and room while the child was under treatment for the disease. We believe that the prompt removal of cases of scarlet fever to a contagious hospital, well equipped, and managed by the Board of Health, will greatly diminish the danger of the spread of this disease. So positive does the Board feel of this proposition that it thinks it may safely say that a contagious hospital would have prevented all but say twenty cases of the three hundred and eighty reported during the last two years.

Before the schools closed in June the disease was fully eradicated.

Since that time cases have only occasionally appeared. During the year, one hundred and thirty-two cases altogether have been reported, as against two hundred and fifty-four cases in 1892.

Diphtheria, of all diseases, is the most treacherous, deceiving even the experienced physician. One day apparently mild, the next it has its victim so firmly clutched by the throat that the most skilful treatment is of no avail. When once the deadly character of this disease is appreciated,

the public will insist upon the use of as radical measures to prevent its increase as are now employed to prevent the spread of small-pox, and we believe that such measures would go far to stamp it out. In Massachusetts, during the year 1892, there were two deaths from small-pox, while there were nine hundred and twenty-eight from diphtheria. In the whole United States, omitting North Dakota, it is reported that, in the same year, there were only one hundred and six deaths from small-pox. This shows that there were in 1892 only one-ninth as many deaths from small-pox in the United States as there were from diphtheria in the State of Massachusetts alone.

Several cases are detailed in the report, illustrating the value of isolation and removal to a hospital provided for contagious diseases. It is almost needless to say that no effectual isolation can be made in all instances without a contagious hospital to which patients may be promptly removed, and it is as a means by which to effect absolute isolation of these dangerous cases that the hospital now nearly finished will demonstrate its greatest value to the city.

We wish at this point to call attention to a matter which to many may appear trivial, but should not be overlooked by those seeking out the methods by which disease is propagated. Upon a visit of our Board to the public schools we found a custom prevailing in many of them of collecting the children's pencils at night and dealing them out promiscuously the next morning. We believe that this custom is a bad one; and we are pleased to say that, on our suggestion, the superintendent of schools caused a rule to be established that each scholar should have his own individual pencil.

It has long been known that, upon reopening the schools after a vacation, infectious diseases seem to take a fresh impetus, and, on the other hand, when the schools are closed, such diseases seem to relinquish their hold upon the community. We therefore believe that during the long summer vacation, the school houses should not only be cleaned in the usual manner, but also thoroughly fumigated and disinfected from top to bottom, and the basements thoroughly whitewashed.

A contagious hospital is now being built, consisting of two wings and a dwelling-house, all connected by long corridors, one wing being for scarlet fever cases and one for diphtheria cases, each capable of accommodating ten patients; and each is so constructed that it can at any time be enlarged at a comparatively small expense, should occasion require.

Under the plumbing act, as it stands, a board of examiners has been organized, consisting of the present chairman of the Board of Health, the present inspector of buildings, and a practical plumber who was chosen by the Board of Health as the third member.

The Board has adopted a system of registering plumbers who were in business at the time the act took effect, that is, on or before July 10, 1893.

To each plumber registering his name a certificate has been issued certifying that he was engaged in the business prior to that date. These certificates have proved of great practical convenience to the plumbers of the city who do work in other places by enabling them to readily prove the fact that they were engaged in business prior to July 10, 1893, and therefore entitled to pursue their calling without a license.

Altogether about 1,100 connections have been made with the public sewer. The total estimated number of connections made and to be made is 2,500.

#### WARE.

A careful investigation of the sanitary condition of the buildings and premises in town was made early in the year by agents, who were appointed for the purpose, and who were furnished with printed blanks containing various inquiries, upon which they recorded their answers. At a later time a second visitation was made by these inspectors where it seemed desirable to the Board that it should be done. In this way accurate and complete information was secured as to our sanitary condition.

In compliance with an act of the Legislature passed during the year, the Board prepared a set of by-laws in relation to plumbers and plumbing work, which were adopted by the town, and which are now operative. These by-laws require that those who newly enter the business of plumbing should pass an examination and obtain a license, which must be renewed each year that they continue in business. All plumbing work, except repairs of leaks, must be done only after proper notice given the Board of Health or its appointed agents, and must be approved by the Board after examination by an inspector of plumbing appointed for the purpose.

#### WELLESLEY.

No cases of typhoid fever have been reported to the Board during the year.

There have been several instances in which the advice of the Board has been sought in regard to sanitation, and in all cases the suggestions made have been readily complied with.

The Board would respectfully call to mind the fact that householders are required by law, no less than physicians, to report cases of contagious disease occurring within their respective families.

#### WESTBOROUGH.

In no instance has the Board been forced to resort to legal measures to secure compliance with its requests.

The general health of the inhabitants of the town has been comparatively good. There has been no epidemic disease, and only four cases of contagious disease dangerous to the public health have been reported.

## WESTFIELD.

At the town meeting, held April 8, it was voted :—

That the Board of Health is hereby instructed to compel persons owning, leasing or maintaining any building, to connect with the public sewer, as provided in chapter 132 of the Acts of 1890, on or before the first day of January, 1895.

After mature deliberation your Board decided that the best interests of the public health demanded immediate action, and instructed its clerk to formulate a notice for compulsory entrance. Five hundred of these notices were sent to property owners on the south side of Westfield River. Entrances were made the entire season as rapidly as the property owners could secure attention from the plumbers and drain-layers. Three hundred and fifty-four sewer applications were made, representing the entrance of three hundred and seventy-one buildings, which includes five hundred and eighteen families, besides eight blocks, two churches, one school building, three shops and one stable.

The Board established certain limits in the town, within which the keeping of swine was prohibited, and provided that any and all swine, and any pen or other inclosure in which swine are kept, outside of said districts, shall be kept in a condition of neatness and cleanliness acceptable to the Board of Health.

## WESTFORD.

The physicians were prompt in notifying the Board of all infectious or contagious diseases, and where quarantine was established we allowed it to remain until the physician in charge of the case notified us that it was unnecessary. Disagreeable as it was to be shut off from their usual freedom, members of the families where these infectious diseases prevailed readily complied with the regulations, and did much to prevent the spread of the disease. Householders do not seem to understand that the law requires them as well as physicians to notify the Board of Health if they are knowing of infectious or contagious disease within their family or house. The law is very plain, and a heavy penalty is provided for non-compliance with it. But two householders have complied with the law the past year.

## WHITMAN.

The difficulties arising from lack of a sewage system, and the fact that a great deal of the land in Whitman is so low that deep cesspools cannot be dug, have been thoroughly described in preceding reports, and it is hoped that at some future time the desired system may be established. The town has not suffered from many cases of contagious diseases the past year, but *all cases* which have come to our knowledge have been promptly reported

to the State Board of Health, entered on our records and reported to the school committee according to law. When necessary, conspicuous red cards with the name of the disease in large letters have been posted on the premises where an infectious disease was known to exist.

#### WILLIAMSTOWN.

The Board has attended to the usual matter of nuisances, which have been promptly abated. In connection with board of selectmen, the Board of Health has assisted in the construction of sewers, an excellent advance in this matter, and it is hoped that the same policy will be continued during the coming year.

#### WINCHESTER.

The Board vaccinated eighty scholars, sixty-one of whom had never been vaccinated before. Some of these had passed through all but the high school.

The Metropolitan sewer is about complete in Winchester, and we hope our local system of sewers will soon be commenced and that, in the near future, Winchester will be supplied with a complete system.

#### WOBURN.

During the year over one hundred complaints were received, concerning existing nuisances, and promptly attended. Among the most prominent was the Pantasote Leather Company nuisance, which had been a cause of complaint for several years, not only by the citizens of our own city, but also by the citizens of the neighboring towns of Reading, Stoneham, Wilmington, Wakefield and Winchester. After a thorough investigation by the Board, they ordered the premises closed until the proper machinery could be introduced to abate the nuisance. The works have not started again, as yet, nor will they be allowed to until all semblance of a nuisance has been abated. A number of complaints were also received from the inspectors of the Boston Water Board and received prompt attention.

#### WORCESTER.

Number of complaints for the year ending Dec. 31, 1893, 1,713. Rooms fumigated, 448.

There were three successful prosecutions by the Board during the year, viz., one for keeping pigs without a license, one under the law regulating contagious diseases among domestic animals, one for doing plumbing work without a license.

Twelve houses, containing thirty-five tenements, were vacated on account of bad sanitary condition.

The general sanitary condition of the city through the year was good. There was a slight increase in the number of deaths over the previous year.

Special efforts were made during the summer months to thoroughly clean the city in anticipation of an invasion of cholera, but owing to the effective national quarantine maintained by the general government its entrance was prevented. As usual, a large number of the cases of typhoid fever were due to causes outside of the city. It is probable that several cases were contracted at Chicago while visiting the Fair. We again call attention to the great necessity of a hospital for the care of contagious diseases. The need of such an institution has been, if possible, more forcibly brought to our attention during the year just closed by the appearance of contagious diseases in several of the institutions of our city that are devoted to benevolent and charitable purposes, thereby impairing, if not altogether preventing, their usefulness for the time being.

The board has encouraged in every practicable way the use of the new remedy, antitoxin, and with very gratifying results. The length of the disease, in cases where this remedy was used, has been much reduced, and in some cases lives have been saved which in all probability would have been lost under any other treatment. Of the four fatal cases, two were treated in this way and two were not.

## SOMERVILLE.

|                                                                        |     |
|------------------------------------------------------------------------|-----|
| Number of nuisances abated, . . . . .                                  | 814 |
| Number of nuisances referred to board of 1896, . . . . .               | 173 |
| Number of nuisances complained of, . . . . .                           | 987 |
| Number of complaints (many covering more than one nuisance), . . . . . | 507 |
| Number of notices mailed, . . . . .                                    | 480 |
| Number of notices served by constables, . . . . .                      | 19  |

In addition to the above, many nuisances have been abated on verbal notice from the agent without action by the board, and of which no record has been made.

Six cases of glanders have occurred during the year. Prompt action was taken in every case, and the horses have been killed.

## TAUNTON.

The board has advocated the isolation of suspected cases of diphtheria, especially where there are two or more children in the family or house, without waiting for a full development of the disease.

Early in the year the board of health invited the co-operation of the school teachers to aid in preserving the public health. To this end printed postal cards directed to the board of health were distributed to each teacher, whereon they were to indicate the absence of any pupil with suspected illness. Upon receipt of the card the physician of the board visited the scholar. A large number of cases so indicated have been examined, and, while a large majority of cases found were of the kind incident to childhood, suspicious cases of contagious disease have been found, the child isolated and children in the house kept from school.

## WAKEFIELD.

Regulations for the inspection and testing of plumbing work were made and have been enforced. The result has been highly satisfactory, the quality of the work done being so much improved as to far outweigh the additional cost to the town of having the inspections made. We wish to impress upon the town the absolute necessity of some sewerage system in the very immediate future, as there are in certain portions of the town nuisances that cannot be entirely abated under present conditions.

# GENERAL REPORT.

---

The contents of the present volume comprise a report of the general work of the State Board of Health for the year ending Sept. 30, 1895, and of that which relates to Water Supply and Sewerage for the calendar year 1895.

This first portion, the general report, paged in Roman numerals, includes a brief statement of the work done under the statutes which define the work of the Board, and contains a summary of the vital statistics of the State for the year 1894.

The second part of the report, paged in Arabic numerals, contains the fuller details of the work of the Board, under the acts relating to Water Supply and Sewerage, Food and Drug Inspection, Reporting of Infectious Diseases and such papers relating to special topics the Board has deemed it desirable to publish.

The following members comprised the Board in 1895 : —

HENRY P. WALCOTT, *Chairman.*

FRANK W. DRAPER.  
HIRAM F. MILLS.  
JAMES W. HULL.

GERARD C. TOBEY.  
CHARLES H. PORTER.  
JULIAN A. MEAD.

Dr. J. A. Mead of Watertown was appointed in October, 1895, to fill the place made vacant by the death of Dr. J. W. Hastings. Dr. F. Mills' term expired in May, 1895, and he was reappointed for seven years.

During the year 1895, in addition to the regular routine work of the Board, the following special lines of work have been prosecuted : —

Under the provisions of chapter 426 of the Acts of 1894, the contract made with the Eastern Dredging Company for the purpose of digging certain portions of the Concord and Sudbury rivers was completed under the direction of the Board.

Under the organic act creating the Board and requiring it to "take cognizance of the interests of health and life among the citizens of the Commonwealth," the Board has provided a continuous supply of anti-toxin, for use throughout the Commonwealth, for the purpose of diminishing the mortality from diphtheria, and in connection with the same work, has organized a bacteriological department for the purpose of experimental and executive work in the investigation of infectious diseases.

The duties of the Board as defined by the statutes have not only been increased but have also been changed in their character since the establishment of the Board in 1869. At that time the work of the Board as set forth in the organic law of June, 1869, was entirely of an advisory nature.

The first act of the Legislature giving to the Board executive powers was the offensive trade act of 1871, whereby the Board was authorized, after due notice and hearing, "and if, in the judgment of the Board, the public health or the public comfort and convenience so required," to order parties to cease and desist from further carrying on such trades or occupations.

By an act of 1878 authority was given to the Board to "have general supervision of water supplies" and to investigate the pollution of them and its causes. It was also empowered to issue orders for the prevention of such pollution. This act was repealed in 1884; but in 1886 another statute was enacted, the scope of which was much broader and more effective in its operation, since it not only authorized the Board to make experiments and investigations in the line of water and sewage purification, but made it incumbent upon all cities, towns, corporations, firms and individuals to seek and obtain competent advice before introducing systems of water supply and sewerage. Liberal appropriations were provided for carrying out its provisions.

In 1882 an act was passed to prevent the adulteration of food and drugs and conferring on the Board the authority to enforce the same. The operations of the Board under this act have been reported in each of the annual reports of the Board during the past thirteen years.

Other acts of minor importance have from time to time been enacted, increasing gradually the executive functions of the Board while its advisory powers have not been diminished. Among the

utes of this character may be named the act relating to ice supplies, the supervision of crematories and the act giving to the Board ordinate powers with local boards of health in the prevention of spread of contagious diseases.

### INFECTIOUS DISEASES.

No serious epidemic occurred during 1895. So far as can be seen from the returns of infectious diseases made to the Board under statutory provisions *diphtheria* had increased slightly over the prevalence of the previous year, but in consequence of improved methods of treatment had not proved so fatal as in former years. Deaths from *scarlet fever* were much fewer than those of either 1893 or 1894, those from *typhoid fever* were slightly less than those of 1893 or 1894, and those from *measles* were greater than those of 1894 but less than those of 1893.

#### *Small-pox.*

During the year 1895 not a single death from small-pox has been reported to the Board, and there was but one recorded case of illness in this disease, as compared with a total of 185 cases and 32 deaths in the previous year. Had this single case been cared for in the State where the disease originated, as ought to have been done, he should have been able to record an absolute immunity from small-pox throughout the year. The patient in this case was a student at Yale College, where he was taken ill and was allowed to return to his home in Massachusetts, travelling through two States by public conveyances. Had unvaccinated persons or those not recently vaccinated been exposed to him on the way, the consequences might have proved disastrous. The facts in this case are presented in conformity to the usual blank form employed in the reports of recent years.

| No. | Place.   | Date of Report. | Nationality.   | Age. | Sex. | Occupation. | Vaccinated. | Number of Scars. |
|-----|----------|-----------------|----------------|------|------|-------------|-------------|------------------|
| 1   | Andover. | March 8         | United States. | 18   | M.   | Student.    | Yes.        | 2                |

*Other States and Provinces.*—While Massachusetts was so nearly exempt from the invasion of small-pox, other States suffered consid-

erably from its presence during the year. In compliance with the interstate resolutions adopted at Toronto in 1886 notices were received from the following States and provinces with reference to the existence of cases of small-pox during 1895, the sum total being at least 1,348 cases: In Maine 1 case, New Hampshire 19, Connecticut 4, Rhode Island 1, New York 2 (also others, the number not stated), Pennsylvania 327, Maryland 60, Ohio 205 (chiefly in Cincinnati), Michigan 45, Illinois 7, Wisconsin 379 (chiefly in Milwaukee), Missouri 267, Tennessee 3, Minnesota 4, Alabama 1, Oklahoma 7, Ontario 16; total, 1,348.

Notices were also received four times during the year from the immigration office at New York of the arrival of the following steamers with cases of small-pox on board: the "Ems" from Bremen, May 28; the "München" from Bremen, June 19; the "Marsala" (mostly Greeks), October 6; the "California" (mostly Italians), December 3.

The names of immigrants on these steamers destined for Massachusetts, with the places of destination, were also forwarded, and were immediately transmitted by the Board to the local boards of health in the cities and towns to which such immigrants were bound.

### *Typhoid Fever.*

The number of requests which have been made for the assistance of the Board in investigating the causes of typhoid fever has materially lessened within the past two years, the cause being undoubtedly due in a great measure to the continuous introduction of new and purer water supplies for domestic use in cities and towns, and the adoption of methods of protecting existing water supplies from pollution and the purification of certain waters by filtration.

The mortality from typhoid fever in 1894 was only 3.1 per 10,000 of the population.

The following figures represent approximately the mortality from this disease in the different counties of Massachusetts in 1894 per 10,000 of the population living in each county. They show not only a lessened mortality as compared with the figures of earlier periods, but also a greater uniformity in the different counties.

*Death Rate per 10,000 Living from Typhoid Fever in Massachusetts (by Counties), 1894.*

e of the most common means by which typhoid fever is spread  
 g the population is the milk supply. Epidemics of this char-  
 have been investigated by the Board in recent years in Cam-  
 e, Somerville, Woburn, Springfield, Marlborough and Newton.  
 such epidemics in different years have occurred in Cambridge,  
 them apparently due to infection of the milk supply, either at  
 urce upon the producing dairy farms or at the place of collec-  
 or distribution in the city. Hence the importance of securing  
 reatest care in preventing the occurrence of the disease among  
 ns employed either at the dairies or at the places where the  
 cans are handled and cleaned, at the final place of distribution.  
 erson who has the slightest symptoms of typhoid fever should  
 owed to engage in these occupations until complete recovery  
 ken place. Mild or “ambulant” cases are more dangerous  
 severe cases, in which the sick are confined to bed, since the  
 r are far more liable to infect the milk supply, as has been  
 in the investigations conducted by the Board.  
 e following rules recommended by Dr. Russell, senior medical  
 : of health of Glasgow, would, if everywhere enforced upon  
 farms, diminish very greatly the prevalence of typhoid fever  
 : cities and towns : —  
  
 The first and foremost requirement is absolute cleanliness in all the  
 of dairy work.

2. The cow stable should be of ample size, capable of thorough and frequent cleaning; it should be well lighted, preferably by sunlight, and should be well ventilated.

3. To ensure the greatest freedom from milk infection, the farmhouse should be separated from the buildings used for dairy purposes.

4. No person who is suffering from an infectious disease (or one which conveys any suspicion of infection), or who has been in any way in communication with an infected person or thing, should engage in the milk business.

5. The milk of sick animals, or of those which have suspicious eruptions about the udder or teats, should not be sold for food for human beings.

6. The udder and teats, if soiled, should be washed before milking; warm water, soap and towels should be at hand for the use of milkers, who should be instructed to use them before milking.

7. Healthy cattle, healthy attendants, and, above all, perfect cleanliness in dairy work mean money both to the producer and to the retailer of milk.

The following table presents the statistics of mortality from typhoid fever in the cities of Massachusetts from 1871 to 1894, with the mean annual death rates from this cause in five-year groups.

The table shows a notable decrease in the mean annual death rate from typhoid fever in the four years 1891-94, as compared with the period immediately preceding.

Deaths and Death Rates per 10,000 Living, from Typhoid Fever, in Cities of Massachusetts, 1871-94.

*Malarial Fever.*

In addition to the appearance of malarial fever at different points in the State, as detailed in previous reports of the Board, reports have been received by the Board during the past year relative to its appearance in two additional localities, at North Saugus and at Uxbridge.

Notice of its appearance at North Saugus came to the Board in the form of a petition, stating that the city of Lynn had constructed reservoirs in North Saugus for the storage of water, and was about to build another, also that malarial fever had been prevalent in that village since their construction. The petitioners therefore requested the Board "to investigate the matter and to take such action as may be necessary." With a view to affording relief to the petitioners the Board caused an investigation to be made at North Saugus. A house to house visit was made, which resulted in the finding, among a population of about 200 persons, that there had been 21 cases of intermittent fever in 1894 and in the first six months of 1895 there were 13 more. It was also stated that there had been many more cases in 1892 and in 1893. Five households had escaped, mostly on higher ground.

In compliance with this petition the Board held a hearing in August, 1895, at which the board of health of Saugus was represented, together with other citizens of that town and the superintendent of the water works of Lynn. As a result of the hearing, and in view of the facts elicited upon the petition relative to the construction of a new reservoir by the Lynn water board in North Saugus and the effects of such construction on the health of the adjacent community, and in consideration of the methods described by the constructing engineer and the superintendent of said water board with reference to the preparation of the proposed basin and its connections, it was voted "that the State Board of Health deems further action on its part with reference to the new reservoir unnecessary, under existing conditions."

Later in the year information was received that malarial fever was prevailing in Uxbridge, and a request was received from the local board of health of that town that the State Board would investigate the same. An agent was sent to Uxbridge and the investigation is in progress at the time of writing this report.

### *Consumption.*

in keeping with the progress of medical science, and especially with the important discoveries which have been made in the history of infectious diseases, their causes and prevention, the methods of detecting the existence of consumption and the measures taken to prevent its spread form an important part.

Improvements in ventilation in the hygiene of industrial operations, the proper selection and inspection of the food supply, the adoption of improved climatic conditions, the management of dust in the household and workshop, and above all in the proper disposal and destruction of the sputa of the sick, all have without doubt had marked effect in steadily diminishing the mortality from this destructive disease.

In the last annual report (page lxxv *et seq.*) a summary of the vital statistics of consumption was presented, in which its steady diminution during a period of nearly a half century was shown.

With a view of diffusing popular information upon the best methods of preventing tuberculosis the Board issued the following circular in January, 1895, which was distributed throughout the State to health persons (chiefly physicians and boards of health) as would be most likely to appreciate its value and place the circular where it would prove useful in the prevention of the disease.

#### **CIRCULAR OF THE STATE BOARD OF HEALTH RELATIVE TO TUBERCULOSIS OR CONSUMPTION AND THE BEST MEANS FOR PREVENTING IT.**

The object of the State Board of Health in issuing the following circular is to furnish information (1) as to the nature of pulmonary consumption, the conditions which favor its spread, and (3) the best methods of preventing it.

##### *1. — As to the Nature of Consumption.*

Consumption is the most destructive disease of New England, the number of persons annually dying from this cause in Massachusetts amounting nearly six thousand. Modern research places it among infectious diseases.

The specific virus or poison of the disease consists of a minute germ, the bacillus of tuberculosis," which exists in the tissues and expectoration of the sick, and which may in various ways enter the bodies of the well and produce the disease in them. In the proper care and disposal of the expectoration of the sick, it is probable, lies one of the chief methods of preventing the spread of the disease.

## 2. — *Conditions which favor the Spread of Consumption among Human Beings.*

*Defective ventilation.* One of the chief conditions which is favorable to the production of consumption is the continuous and habitual breathing of unrenewed air. Consequently, in workshops, factories, school rooms, public buildings, halls, churches, and the inhabited apartments of dwellings and tenement-houses the absence of adequate means of ventilation favors the spread of consumption.

*Dampness of soil* on which the house stands, and dampness of the immediate neighborhood are favorable conditions for the production of consumption. The occupancy as living or sleeping rooms of apartments which are constantly damp or are partly or wholly underground, undoubtedly has a similar effect.

*Overcrowding* in dwellings, in factories, and in workshops where men and women work for several hours each day, is also a favorable condition for spreading the disease. Density of population increases the liability to this disease. Observations in Massachusetts extending over a period of twenty years (1871-90) show that the deaths from consumption in densely settled districts, as compared with those in sparsely settled districts of the State stood in the ratio of 1,000 deaths in the former to 727 in the latter.

Another factor which favors the spread of this disease is the presence of *dust* in the air of apartments, factories, mills and workshops. Hence occupations or trades in which men, women or children are exposed to the inhalation of irritating dust increase the liability to contract the disease among such operatives. An examination of the reports of the Registrar General of England for several successive years shows that fishermen, who are of all classes the least exposed to dust inhalation, are also comparatively exempt from consumption.

*Insufficient and badly selected food.* While the influence of improper and insufficient feeding upon the predisposition to consumption is not so directly proven as are the effects of certain other conditions, there is yet sufficient evidence to show that a restricted diet or one composed exclusively of single elementary constituents, as for example, the starches alone, and these in too limited quantities, probably predisposes to consumption.

*Intemperance* in the use of alcoholic stimulants has also been shown to act in the same direction.

Undue physical or mental strain, overwork, worry and anxiety, and the prolonged suckling of infants (beyond ten or twelve months) are conditions contributing to the same end.

## 3. — *Preventive Measures.*

Having the foregoing predisposing conditions in view, the measures which are essential for the prevention of this disease may be more clearly understood

1. *The prevention of overcrowding.* In tenements and in dwelling-houses the prevention of overcrowding diminishes the liability to contract tubercular diseases among the occupants.

Hence the adoption of measures which shall counteract the effect of overcrowding is desirable. Ventilation is one of the most efficient of such measures. Adequate ventilation should be provided in all factories, halls, school-houses and other buildings in which people assemble in considerable numbers. Simple methods of ventilation in the living and sleeping rooms of dwellings are also essential to healthy living. Open fireplaces, movable grates in sleeping rooms, provision for admitting fresh air at the windows by special means are all useful precautions.

2. *Household as well as personal cleanliness* is essential to the prevention of consumption. The removal of dust from floors should be practised and care should be taken that such dust is removed by such means as will ensure the least diffusion through the air of rooms during their occupancy.

3. *Occupations.* The selection of a healthy occupation is a matter of small importance.

Sedentary occupations in ill-ventilated apartments and those which expose the workman to the inhalation of dust should be avoided. Different sorts of dust vary in harmful effects. The sharp dust produced in the grinding of needles and steel tools and in the mining of metals is especially irritating, and the mortality from consumption among operatives in such industries is high. Operatives engaged in such occupations may diminish the liability to harm by wearing "respirators" over the mouth and nose, while at work.

In several factories where consumption had made serious inroads upon the operatives, the adoption of measures for the prevention of a dusty atmosphere secured a marked diminution of the prevalence of this disease among the workmen employed in them.

Regular daily exercise in the open air is of the first importance for all persons who are engaged in sedentary occupations.

The owners and superintendents of *factories, mills and workshops* can accomplish much toward the prevention of tuberculosis among the operatives by the introduction of adequate systems of ventilation and heating, and by the use of hard, smooth floors without cracks or crevices.

The dust should be removed from the floors at night, after working hours, and not during the occupancy of the workrooms. The use of moisture in the removal of dust, and careful wiping with damp cloths is preferable to sweeping up the dust when dry. Spitting upon the floor should be forbidden.

4. *Food.* As an essential requisite to the prevention of consumption, diet of sound, wholesome food, in which the chief elementary forms of nutriment are harmoniously combined (the fats, starches and proteids) is necessary. Such a diet should consist mainly of bread and the various

cereals with butter and other fats in generous measure, together with meat, fish and fruits. This does not imply a luxurious or expensive diet, but rather one that is nutritious and easily digested.

The question of the effect of the use of the *meat* and *milk* of *tuberculous animals* does not yet appear to be so well settled as to admit of an unqualified conclusion.

In the absence of absolute and definite evidence, it is therefore desirable that the *meat* of all suspected animals should be cooked thoroughly before using it as food. The *milk* of such animals should be entirely excluded from the food supply.

5. *Overwork, anxiety, worry and exhaustion* should be avoided. Mothers should be advised to *wean suckling infants* by the end of the first year.

### *Disposal of Sputa.*

6. With reference to those who are sick with consumption or tuberculosis, and especially with reference to the possibility that their presence among other human beings may prove a source of danger on account of infection, the following recommendation as to the disposal of the expectoration of consumptives should be especially noted.

Observation and experiments have demonstrated the fact that in this expectoration (especially when dried) lies the chief danger of infection, and hence its proper disposal becomes a matter of prime importance. Therefore, sputa should never be allowed to become dry, and should be destroyed as quickly as possible. Consumptives should be instructed not to expectorate about rooms, in streets or highways, in railway or street cars, or in vehicles of any sort, but should spit into rags which can be burned, or into cups or other receptacles containing a little water or other material which may be thoroughly disinfected before the same is allowed to pass into the drain or sewer. Such receptacles should be cleansed with boiling water.

A healthy person should not sleep in the same room with a consumptive.

### *Disinfection.*

7. Sputa may best be burned when deposited upon pieces of cloth or rags; and when put into cups or receptacles holding water the whole should be disinfected with a saturated solution of carbolic acid, which may be obtained of any reliable druggist.

Disinfection should be practised in the case of rooms or apartments which have been vacated by consumptives or those in which such persons have died. There is a growing belief, supported by observation, that rooms which have been inhabited by consumptive families may become permanently infected, and ought not to be occupied until radical measures have been taken to cleanse and disinfect them. Each room vacated by a

erulous patient should be disinfected and especially the floor and er parts of the walls. For this purpose washing the floor and all wood-k with a corrosive sublimate solution, one part to one thousand (about teaspoonful to a gallon of water) should be practised, and the bed and hing of the last occupant should be submitted to steam disinfection or boiling water. Strong soapsuds also have efficient disinfecting power, may be used for washing floors and woodwork. The disinfection ald be thoroughly done, but especially so in cases where the habits of consumptive in regard to disposal of his sputa have been careless.

as a means of spreading information upon this important subject, local rds of health can undoubtedly accomplish much toward the prevention onsumption, by issuing a circular like the following:—

*The Prevention of Consumption.*

onsumption is the most destructive disease of New England, the number of ons dying annually from this cause in Massachusetts amounting to nearly thousand.

The disease is infectious, and can be communicated from one person to another. chief danger exists in the expectoration of the sick, and if this expectoration arefully destroyed little danger need be feared.

Consumptives should be instructed not to spit upon the floors of rooms, public s, street and railway cars, and other vehicles, nor in the streets, but into pieces cloth, or receptacles made for the purpose, containing water, or a saturated tion of carbolic acid (one part of carbolic acid crystals to about fifteen parts of er). Such bits of cloth should be destroyed by fire, before the sputa become , and other receptacles should be cleansed with scalding water, their contents ing been destroyed or otherwise carefully disposed of. Handkerchiefs which y have been used from necessity should be boiled half an hour before washing. A healthy person should not sleep in the same room with a consumptive. Remember that sputa must never be allowed to become dry.

OFFICE OF THE STATE BOARD OF HEALTH, BOSTON.  
January, 1895.

LOCAL BOARDS OF HEALTH.

Nearly fifty years ago (1850) the sanitary commission of Massa- usetts advised the obligatory appointment of boards of health in ery city and town in the State, and after the establishment of the ate Board of Health in 1869 this Board frequently called attention the need of legislation having this end in view. But not until 1877 was legislation enacted requiring such boards to be appointed a compulsory measure, and even then the requirement applied to ties only. The Board has from time to time urged the necessity further legislation requiring similar action on the part of towns, d especially in the case of those having large populations.

No substantial advance has been made in this direction, however, until the enactment of a law in 1894, of which the following is a copy. This statute (chapter 218, Acts of 1894) was amended later in the session, by the same Legislature, so that the amended act reads as follows : —

[Chapter 218, Acts of 1894, as amended by chapter 473, Acts of 1894.]

**AN ACT PROVIDING FOR THE ELECTION OF BOARDS OF HEALTH IN TOWNS.**

**SECTION 1.** Every town in the Commonwealth may elect a board of health by ballot at the annual meeting of the town, or at a meeting legally warned for the purpose, consisting of three persons, to serve, one for the term of three years, one for the term of two years and one for the term of one year, beginning with the first Monday in April then next ensuing and until their respective successors are chosen and qualified; and thereafter such town shall, at its annual town meeting, choose in the same manner one person who shall hold office for three years from the first Monday of April then next ensuing, and until another is chosen and qualified in his stead. If no such board is chosen the selectmen shall constitute such board of health.

Section 2 was repealed by chapter 473 of 1894.

**SECTION 3.** In each city and town having a population of more than five thousand inhabitants, as determined by the last census, at least one member of said board shall be a physician, and the board shall send an annual report of the deaths in such town to the state board of health. The form of such reports shall be prescribed and furnished by the state board of health.

**SECTION 4.** Section three of chapter eighty of the Public Statutes is hereby repealed. Sections two, twenty-one, twenty-eight, twenty-nine, thirty, thirty-one, thirty-two, thirty-three, thirty-four and thirty-five of chapter eighty of the Public Statutes, and sections one and two of chapter three hundred and thirty-eight of the acts of the year eighteen hundred and eighty-seven, are hereby amended by striking out the words "or health officer," wherever the same occur therein. [*Approved April 7, 1894.*]

The formation of an organization known as the Massachusetts Association of Boards of Health has proved a decided stimulus to local boards in consequence of the advantages secured to its members by means of mutual discussion of the many questions which are constantly occurring in the work of municipal sanitary administration. The members of this organization consist mainly of the members of local boards of health, and of such other persons as are especially interested in public hygiene. Meetings have been held quarterly during the past five years or more, and at each meeting

as relative to the work of municipal boards have been presented for discussion. Committees have been appointed to confer with relative health committees with reference to matters of importance which appear to require further legislation.

The association publishes a quarterly journal in which its transactions appear.

#### OFFENSIVE TRADES.

Two complaints were made to the Board during the year under the provisions of the acts relating to offensive trades, and consequently hearings were held. The board of health of Newburyport rejected the advice of the State Board in regard to a rendering establishment in that city, situated at some distance from the populous part of the city. The secretary conferred with the secretary of the local board, and on visiting the establishment in question found it in an extremely filthy condition, both internally and externally, some twenty or forty carcasses of horses in different stages of decomposition lying unburied upon the surface of the ground, while many others, efficiently buried, had been uncovered by dogs.

Information was received that the premises were subsequently put in good condition and that no further complaints had been made in relation to the same.

#### LOCAL NUISANCES.

A very considerable part of the correspondence received by the Board consists of letters from individuals, or of petitions signed by a greater or less number of citizens, requesting the State Board to remove the local nuisances existing in cities and towns. Often such letters and petitions call the attention of the State Board to the fact that the local board of health has been requested to abate the nuisance but has either refused or neglected to attend to the matter.

So frequent has this class of correspondence become that the State Board has issued a circular which is used as a reply to letters of this character, calling attention to the fact that the State Board has no power or authority to abate an ordinary local nuisance, but that the power is conferred upon the local board of health to take all proper measures in such cases. If the local board of health refuses or neglects to comply with the request of the petitioners, then the matter may be referred to the county commissioners under the provisions of chapter 80, sections 36, 37 and 38, but not to the State Board of Health.

### FOOD AND DRUG INSPECTION.

The importance of an abundant and wholesome food supply, in the preservation of the health and strength of a population, cannot be over-estimated.

The operations of the Board under the provisions of the food and drug acts have in each year from 1883 to the present year been made the subject of a special report, in which are presented the essential particulars of the work accomplished during the year. This report upon food and drug inspection presents a tabular summary of the entire work from 1883 to 1895 inclusive, together with the report of prosecutions submitted to the Legislature, and the reports of the analysts for the year ending Sept. 30, 1895.

From this report it appears that 7,309 samples of food and drugs were examined during the year, at a total cost for inspection, collection, analysis and prosecution of \$11,375.89.

The number of prosecutions conducted in the same year was 92, and the number of convictions was 86, or 93.5 per cent.

### BACTERIOLOGICAL WORK AND ORGANIZATION OF DEPARTMENT.

Hitherto, the principal department of bacteriological investigation conducted by the Board has chiefly been the examination of drinking water supplies with reference to their possible contamination with the germs of typhoid fever and kindred diseases, but the rapid advances which have been made in recent years in the investigation of the natural history of other infectious diseases, and the methods of their prevention and the consequent lessening of mortality from these causes, have led to the extension of this work into other fields.

In the last report of the Board (page cvii) reference was made to the work which had been initiated by the Board for the production of antitoxin and its distribution to boards of health throughout the State. For this purpose the services of Dr. J. L. Goodale were secured. He entered upon his duties with enthusiasm and successfully carried out the plans which the Board had designed with this end in view. To his energy much is due for the successful initiation of this new and important line of work. Since, however, it appeared desirable to enlarge the scope of this department, it was deemed best to obtain the services of an expert, who could devote his whole time

to bacteriological work and at the same time conduct investigations in such new fields of inquiry as might be presented.

For this purpose the Board appointed Dr. Theobald Smith of Washington, D.C., formerly Chief of the Division of Pathology of the Bureau of Animal Industry of the Department of Agriculture. A laboratory was established in the building known as the Bussey Institution, near the Forest Hills station of the New York, New Haven & Hartford Railroad, where facilities were also offered for stabling and caring for the horses required for antitoxin production.

More recently the work of examination of cultures in suspected cases of diphtheria was entered upon, and still later the examination of sputa suspected of containing the bacilli of tuberculosis. The appearance of malarial fevers in regions hitherto uninvaded has also suggested the examination of the blood of malarial patients, and with this end in view circulars have been issued to local boards of health offering the services of this department in making the necessary diagnostic examinations.

A report upon the production of antitoxin may be found among the special papers in this volume, and in the next annual report further information will be given in relation to the other branches of bacteriological investigation.

#### LEAD POISONING BY MEANS OF THE USE OF LEAD PIPE FOR THE CONVEYANCE OF DRINKING WATER.

In a State in which one hundred and fifty municipalities are supplied with water from nearly as many distinct and separate sources, the quality of the water furnished to consumers presents very many points of difference, as is specially shown by the reports of the Board upon the examination of water, issued during the past seven years.

In the present report (page 30) reference is made to the present water supply of one town (Kingston), where a considerable number of cases of lead poisoning occurred during the past year.

The water furnished to consumers in this town appears to have acted with unusual power upon lead pipes, especially upon those which were comparatively new. It was also found on investigation that lead pipe was used in Kingston to an unusual degree for house connections with the street pipes, and long lines of such service pipes, several hundred feet in length, were employed in not a few instances.

These facts, together with a careless use of water which had been allowed to stand in the pipes over night, undoubtedly accounted for the cases of illness, some of which were severe.

An investigation is now being conducted by the Board with reference to the question of lead poisoning by drinking water supplies in general, and will be reported upon in a future report.

**THE STATE BOARD OF HEALTH EXHIBIT AT THE COTTON STATES  
AND INTERNATIONAL EXPOSITION AT ATLANTA, GEORGIA.**

The following invitation was received in August, 1895, from the Secretary of the Board of Managers representing Massachusetts at the Atlanta Exposition:—

BOSTON, MASS., Aug. 21, 1895.

*To the Secretary, Massachusetts Board of Health, State House, Boston.*

DEAR SIR:—It is the desire of this Board that your department make an exhibit at the Cotton States and International Exposition, Atlanta, Ga., to be located in the State building to be erected on the Exposition grounds. We understand that you are willing to make an exhibit of this kind.

If convenient, as a matter of record, we should like to know what exhibits you intend to or can make conveniently. I suppose it will be scarcely possible for you to give this statement in much detail at this time. Can you make an approximate estimate of the probable cost of such an exhibit to the State, including of course, the getting of it to Atlanta, putting it up, and properly returning it into your possession?

Very truly yours,

HENRY G. KITTREDGE,

*Secretary.*

The Board accepted the invitation thus tendered to them and placed the work of preparing the exhibit in charge of Prof. Wm. T. Hedgwick, who had successfully managed the Board's exhibit of 1893 at the Columbian Exhibition at Chicago.

Ample room was furnished for the exhibit in the second story of the Massachusetts building at the Atlanta Exposition.

The material of this exhibit was essentially the same as that which was presented at the Exposition at Chicago in 1893, and was detailed in the twenty-fifth annual report of the Board (page xviii), with such additions as represented the progress made by the Board in its sanitary work during the two years which had elapsed since the World's Fair. These were chiefly the maps, plans and report

showing the Metropolitan water supply, plans of the filter for purifying the city water supply of Lawrence, photographs of the anti-toxin laboratory at Forest Hills, and plans of the more recent systems of sewage disposal adopted by cities and towns since 1893.

The directors of the Exposition, acting upon the suggestion of the jury of award, awarded the grand prize, or gold medal, to the State Board of Health "for a comprehensive exhibit of the means and methods adopted by the Board to promote the health of the people of the State and the country."

### MANUAL OF HEALTH LAWS.

The Board has published, at intervals of three or four years since 1882, a digest of the laws relating to public health in force in this Commonwealth, each revision containing all of the new health statutes and amendments up to the date of publication, together with such decisions of the supreme court as have been made upon cases which have been referred to it under these statutes. This manual has proved a very useful aid to the work of local boards of health, as well as to all persons connected with or interested in sanitary work.

### WATER SUPPLY AND SEWERAGE.

The engineering department of the Board was established in 1886, by authority of the new power conferred upon the Board by the enactment of chapter 274 of the Acts of that year. F. P. Stearns, C.E., was appointed as engineer of the Board in September, 1886, and continued as its engineer till August, 1895, when he was appointed engineer of the Metropolitan Water Board, and X. H. Goodnough was appointed engineer of the State Board of Health.

It is difficult to estimate the extent of the useful results accomplished under the provisions of this act during the ten years since it became a law of the Commonwealth.

An experiment station has been established for the purpose of investigating the important subjects of filtration of water and of sewage; thousands of samples of water, of sewage, of sands, gravels and other soils have been examined; rivers, brooks, ponds, lakes and springs have been visited and investigated in reply to applications for advice with reference to their usefulness for the purposes of water supply or to the prevention of their pollution; hearings and conferences

city and town authorities have been frequently held, and advice been given under the statutes to municipal authorities, corporations, firms and individuals in at least four hundred instances, and in cases in which the value involved has ranged from that represented by some comparatively small seashore water supply to those of the large cities involving several millions of dollars.

In this department have been planned several of the most important and extensive schemes relative to the water supply and sewerage of large communities.

These were the North Metropolitan sewerage system, providing for the sewage disposal of eighteen municipalities, most of which are on the Charles River. This plan was reported to the Legislature in 1889, and was then ordered to be constructed and is now in operation. The cost of the works has been about \$5,500,000.

The planning of the Metropolitan water supply was entrusted to the Board and was reported upon in 1895, and is now in course of construction.

This extensive work will provide a water supply for twenty-eight municipalities, containing at present about one million inhabitants, at an estimated cost of \$27,000,000.

Other duties entrusted to the Board of a similar nature were the improvement of the Concord and Sudbury rivers, the improvement of the Neponset River, the reporting of a system of sewerage and sewage disposal for Salem and Peabody, and, in connection with the Metropolitan Park Commission, the improvement of the lower portions of the Charles River, and later still, as a joint Board with the Harbor and Land Commission, an investigation of the Green Harbor and marshes.

The work of the Board in this department for the year 1895 is presented in this report. It includes the following topics: Advice to cities and towns, details of the examination of water supplies and rivers, summary of water supply statistics and records of rain, the hardness of water and methods by which it is determined, experiments upon the purification of sewage and water at the Lawrence Experiment Station, methods of determining the numbers of bacteria in sewage and water, and an account of the sewage disposal works now in operation in the State.

**THE SANITARY CONDITION OF THE NEPONSET MEADOWS.**

During the session of the Legislature of 1895 a hearing was held by the legislative committee on public health with reference to the condition of the Neponset meadows and their effect upon the public health. These meadows occupy a large extent of territory upon both banks of the Neponset River from Walpole through the towns of Norwood, Canton, Hyde Park and Milton, nearly to the sea.

As a result of this hearing the Legislature enacted the following resolve : —

[CHAPTER 83 OF THE RESOLVES OF 1895.]

**RESOLVE DIRECTING THE STATE BOARD OF HEALTH TO INVESTIGATE THE  
SANITARY CONDITION OF THE NEPONSET MEADOWS.**

*Resolved*, That the state board of health be directed to investigate the sanitary condition of the meadows of the Neponset river and the beds, shores and waters of said river in the towns of Canton, Sharon, Norwood, Dedham, Milton and Hyde Park, and report whether their condition is dangerous or injurious to the public health by reason of stagnant water or refuse from manufactories, or other causes. If said board shall find that the condition of the meadows or of the beds, shores or waters is dangerous or injurious to the public health, they shall recommend some plan for improving their sanitary condition and for the removal of any nuisance therefrom, and report the same to the next general court. The board may expend a sum not exceeding three thousand dollars in carrying out the provisions of this resolve. [*Approved May 9, 1895.*]

Investigations with reference to the subject contemplated by this resolve were still in progress at the time of printing this report.

**THE SEWAGE DISPOSAL AND DRAINAGE OF SALEM AND PEABODY.**

The Legislature of 1895, after consideration of a petition from the mayor of Salem for a commission to report upon a system of sewerage and sewage disposal for Salem and Peabody, enacted the following resolve : —

[CHAPTER 112 OF THE RESOLVES OF 1895.]

**RESOLVE RELATIVE TO SEWAGE DISPOSAL AND DRAINAGE IN SALEM AND  
PEABODY.**

*Resolved*, That the state board of health is hereby authorized and directed to consider and report a general system of drainage and sewerage for the city of Salem and town of Peabody, or for such parts of said city and town

t all of which shall be wholly within either of said municipalities, as may, the opinion of said board, be best drained by said system. It shall be a duty of said board :— First. To designate the portions of said city and town which shall be tributary to and embraced in the district and system to be so reported, and to define the same by their report, with plans and maps. Second. To define and show, by suitable plans and maps, such trunk line and main branches as it shall recommend to be constructed, with outlet. Third. To consider the various methods of disposal of sewage and the application of such methods to any portion of the territory herein mentioned ; and to define the methods by which said city and town, or parts of said city and town, may utilize said trunk line and main branches as an outlet of a stem of sewerage and drainage for said city and town and said parts of said city and town respectively ; and to show the same by plans and maps. Fourth. To employ such engineering and other assistance as may be necessary for carrying out the objects of this resolve, and to cause such surveys and levels to be made as will enable said board to determine with accuracy the location and grades of said trunk line and main branches, and to cause such surveys and levels in said city and town, and parts of said city and town, as will enable said board to determine with accuracy the methods which said city and town, and parts of said city and town, may respectively utilize said trunk line and main branches, and to report such methods and plans showing the main lines by which each may so provide for itself a stem of sewerage and drainage with its outlet into said trunk line or main branches. Fifth. To define the size and capacity of said trunk line and main branches, and the materials of which they should be constructed and manner of construction, and such other particulars as will enable said board to determine the probable expense thereof ; and to ascertain and report the cost of the construction of said trunk line and main branches and outlet, and to report a recommendation as to the methods of apportioning said cost. All expenses incurred by said board under the provisions of this resolve shall be reported to the governor and council, and all such expenses when proved by them shall be paid out of the treasury of the Commonwealth ; but the total expenditure shall not exceed three thousand dollars. The Commonwealth shall be reimbursed for such expenditure under this resolve when it shall have been approved by the governor and council in the following manner :— The town of Peabody and the city of Salem shall each pay such proportion of the above expenditure as the said board shall deem to be equitable, and the amounts so to be paid by each shall be assessed and collected by the treasurer of the Commonwealth at the time required for the payment of the state tax of said town and said city respectively. Said board shall make all reports required by this resolve to the general court on or before the first Wednesday of January in the year eighteen hundred and ninety-six. [Approved May 29, 1895.]

The State Board of Health began the work required by the foregoing resolve in June, 1895, but the time within which the report was to have been submitted to the Legislature being insufficient for the work in hand, the succeeding Legislature extended the time to July 1, 1896.

#### HEALTH OF TOWNS.

A digest of the principal facts of importance published in the annual reports of local boards of health occupies the final pages of this report. The table containing the number of cases and deaths from certain infectious diseases with the ratio of fatality has been transferred from this portion of the report to that part which is entitled "Statistical Summaries of Disease and Mortality."

#### ROUTINE WORK OF THE BOARD.

During the year ending Sept. 30, 1895, the Board held meetings at least once in each month during the year. Meetings of such of the standing committees as were necessary for the transaction of business were also held from time to time, as well as joint sessions with such other boards or commissions as were prescribed by the Legislature.

The office of the Board has been open throughout the year, as prescribed by the Public Statutes, chapter 21, section 10,\* for the transaction of its authorized business.

Advice has been very frequently given at the office and by mail to local boards and to individuals in regard to sanitary matters, and many visits have been made by the secretary, the engineers and other experts to cities and towns for the purpose of making investigations and giving advice.

The work of the office has become materially increased during the year, in consequence of being made a central office for the distribution of antitoxin to local boards of health, hospitals and physicians in private practice.

The statistics of mortality compiled from the weekly postal card returns from the registering authorities of cities and towns have been published weekly during the year in the form of a bulletin, which also contains, once in each month, a report of the work done in the line of food and drug inspection, together with the prosecutions

---

\* Office hours, 9 A.M. to 5 P.M. ; Saturdays, 9 A.M. to 2 P.M.

der the food and drug acts, and other important information to the work of this department. In addition to these items also published in the same bulletin a weekly report of the of cases of infectious diseases reported by the local boards State Board of Health.

Following table presents certain statistical data relative to the work of the Board : —

#### STATISTICAL TABLE FOR THE YEAR ENDING SEPT. 30, 1895.

|                                                                      |            |
|----------------------------------------------------------------------|------------|
| number of samples of foods and drugs examined during the year,       | 7,309      |
| of milk examined (included in the foregoing), . . . . .              | 3,794      |
| number examined since beginning of work in 1883, . . . . .           | 67,756     |
| number of samples of milk examined since beginning of work . . . . . | 34,421     |
| of prosecutions against offenders during the year, . . . . .         | 92         |
| of convictions during the year, . . . . .                            | 86         |
| of fines secured during the year, . . . . .                          | \$2,625 00 |

#### Employed in general work of Board at central office, State House : —

|                        |   |
|------------------------|---|
| Secretary, . . . . .   | 1 |
| Chief Clerk, . . . . . | 2 |
| Manager, . . . . .     | 1 |
| —                      | — |
| Total, . . . . .       | 4 |

#### Employed at central office, State House, Boston, for food and drug

|                                                   |   |
|---------------------------------------------------|---|
| Commissioners, chemists and assistants, . . . . . | 2 |
| Total, . . . . .                                  | 1 |
| —                                                 | — |
| Total, . . . . .                                  | 3 |
| —                                                 | — |
| Total, . . . . .                                  | 6 |

#### Employed at laboratory (Bussey Institute) : —

|                       |   |
|-----------------------|---|
| Analyst, . . . . .    | 1 |
| Assistants, . . . . . | 3 |
| —                     | — |
| Total, . . . . .      | 4 |

#### UNDER THE PROVISIONS OF CHAPTER 375, ACTS OF 1888.

##### Requests for advice from cities, towns and others : —

|                                                |    |
|------------------------------------------------|----|

| Chemists, . . . . .                      | 2           |
| Bacteriologists, . . . . .               | 3           |
| Other assistants and laborers, . . . . . | 5           |
|                                          | <b>— 10</b> |

**Total ordinary force employed under chapter 375, Acts of 1888, . . . . . 23**

**Total ordinary force in all departments, . . . . . 37**

The number of applications for advice under the provisions of chapter 275, Acts of 1888, received since July, 1886, when the act relating to water supply and sewerage first went into operation, is as follows: —

|                 |    |                         |            |
|-----------------|----|-------------------------|------------|
| 1886, . . . . . | 8  | 1892, . . . . .         | 56         |
| 1887, . . . . . | 22 | 1893, . . . . .         | 51         |
| 1888, . . . . . | 28 | 1894, . . . . .         | 53         |
| 1889, . . . . . | 38 | 1895, . . . . .         | 52         |
| 1890, . . . . . | 23 |                         |            |
| 1891, . . . . . | 53 | <b>Total, . . . . .</b> | <b>384</b> |

\* Not including the force employed upon the metropolitan water supply investigations, improvement of the Charles, Concord and Sudbury and Neponset rivers, or Salem and Peabody sewerage.

† The chief chemist and biologist, although located at the Massachusetts Institute of Technology, have the oversight of the chemical and biological work at the Lawrence Experiment Station.

## RECOMMENDATIONS.

The following recommendation was made to the Legislature at the beginning of the session of 1896: —

The Board recommends the continuance of its investigations now being carried on as authorized by the provisions of chapter 375 of the Acts of 1888. For this purpose, and to make the necessary investigations in order to advise cities, towns, corporations and individuals in regard to the best methods of assuring the purity of intended or existing water supplies and the best method of disposing of sewage, and to carry out the other provisions of chapter 375 of the Acts of 1888, the Board estimates that the sum of \$30,000 will be required.

## EXPENDITURES.

The work of the Board is conducted under the provisions of several statutes, and for its different departments of work these appropriations are annually made, one for the general work of the board, one for the inspection of food and drugs and a third for carrying out the provisions of chapter 375 of the Acts of 1888, relating to the protection of the purity of inland waters. In addition to the foregoing, special appropriations have been made from time to time, on occasion has demanded, for the purpose of enabling the Board to conduct special lines of investigations.

The appropriations for the different departments of work in 1895 were as follows: —

|                                                                 |                 |
|-----------------------------------------------------------------|-----------------|
| For the general work of the Board, . . . . .                    | \$15,800        |
| For food and drug inspection, . . . . .                         | 11,500          |
| For carrying out the provisions of chapter 375, Acts of 1888, . | 30,000          |
| Total, . . . . .                                                | <u>\$57,300</u> |

In addition to the foregoing regular lines of work the Board was authorized to expend a sum not exceeding \$3,000 for carrying out the provisions of a resolve directing the Board to "investigate the sanitary condition of the Neponset meadows,"\* and a similar amount for the purpose of devising a system of "sewage disposal and drainage in Salem and Peabody."†

\* Chapter 83 of the Resolves of 1895.

† Chapter 112 of the Resolves of 1895.

The expenditures in 1895 under the foregoing appropriations were as follows : —

*General Expenditures Sept. 30, 1894, to Sept. 30, 1895.*

---

## IMPROVEMENT OF THE CONCORD AND SUDBURY RIVERS.

---

In the last annual report of the Board (page cviii) reference was made to the enactment of a statute of 1894 providing that the Board should conduct certain operations upon the Concord and Sudbury rivers for the purpose of improving the condition of the meadows along their banks.

After conducting this work as directed, the Board made the following report to the General Court in February, 1896, under the title House Document No. 891 : —

### COMMONWEALTH OF MASSACHUSETTS.

Boston, Feb. 6, 1896.

The improvement of the Concord and Sudbury rivers has been carried on under the authority of chapter four hundred and twenty-six of the acts of one hundred and ninety-four, section one, which is as follows : —

The State Board of Health is hereby authorized and directed to expend during the present year a sum not exceeding twenty thousand dollars, in dredging the Concord and Sudbury rivers above the dam at North Billerica and removing the weeds from said rivers, and in such other measures as shall, in the opinion of the board, tend to the restoration of the marshes along the said rivers to their original condition and to the abatement of malaria and other perils to the health arising from the present state of the same. [*Approved May 24,*

It is also provided in the act that one-half the expense incurred shall be borne by the owners of lands benefited by the improvement, the other half being borne by the state.

The portion of the Concord and Sudbury rivers referred to extends from a point across the Concord River at North Billerica for a distance of about five miles up-stream to a point in Wayland. Within this distance there are a large number of bars over which the water was only from two feet in depth in the summer season. At these shallow places there is usually a rank growth of weeds, greatly obstructing the flow of the

The subject of the improvement of these meadows has been brought to the attention of the legislature from time to time for many years. Old reports refer to petitions to the legislature in sixteen hundred and thirty-six and again in sixteen hundred and forty-five, on account of the wetness of these meadows. Other petitions in seventeen hundred and forty-two, seventeen hundred and eighty-nine and eighteen hundred and sixteen are also referred to, and previous to eighteen hundred and sixteen and since that time there has been much litigation between the meadow owners and the owners of the dam at North Billerica and the city of Boston, which formerly let down water from compensating reservoirs in Hopkintown and Marlborough. During the years from eighteen hundred and fifty-nine to eighteen hundred and sixty-two the matter was before the legislature, and in eighteen hundred and sixty an act (chapter two hundred and eleven) was passed, appointing three commissioners with authority to lower the dam at North Billerica thirty-three inches. In eighteen hundred and sixty-one by chapter one hundred and fifty-four the act of eighteen hundred and sixty was suspended until the first day of May, eighteen hundred and sixty-two, and a commission was appointed to ascertain whether the dam at North Billerica caused the flooding of the meadows. The report of this commission and its extended surveys formed the basis for the act of the legislature in eighteen hundred and ninety-four. Some of its conclusions were as follows:—

“Fourth. Neither any change which can be made in the height of the dam, nor removing the dam altogether, will, alone, afford substantial relief to the meadows.

“Fifth. Keeping the river clear of weeds will, alone, in the ordinary state of the river, reduce the level of the water surface at the great meadows in Wayland and Sudbury six inches; but this will not afford substantial relief to the meadows.

“Sixth. Removing all obstacles to the flow of the water except the dam at North Billerica, and leaving the dam at its present height, will not substantially relieve the meadows.

“Eighth. The meadows can be effectually relieved only by reducing the height of the dam thirty-three inches or more; cutting out the Fordway and other bars, and deepening the shallow places in the river to such an extent that they shall cease to form any obstruction to the free passage of the water in the ordinary condition of the river; straightening the channel in a few places; and thereafter keeping the river free from weeds. In this way the meadows may be so relieved as to become fit for cultivation and valuable.”

The expenses of this commission amounted to \$18,730. Chapter one hundred and forty of the acts of eighteen hundred and sixty-two repealed the act of eighteen hundred and sixty for removing the dam.

on the passage of the act of eighteen hundred and ninety-four the board took the matter immediately under consideration and succeeded in carrying out the original plans made by the commission of eighteen hundred and eighty-one, also a profile showing the effect of various changes, such as the raising of the dam, the removal of weeds and the excavation of the bars, in addition to the lowering of the dam. Note-books containing the original plans were also obtained.

The method of operating the water power at North Billerica during the period covered by the investigations was found to be for some reason entirely different from what it was in 1861, the water in the millpond under ordinary river conditions now being drawn from twelve to eighteen inches below the top of the flashboards in the day time, but filling up and running freely over the flashboards again at nine or ten o'clock at night; whereas in 1861 the water was almost invariably above the top of the flashboards throughout the day except when the water was purposely maintained at a low level. In account of this change in the method of operation, the old report gives little information as to the effect of lowering the water at the dam during the day by the ordinary operation of the mills upon the water in the pool above the Fordway bar.

The diversion of water from the Sudbury River watershed by the city of Boston has caused a lowering of the water in the summer season along the river below the point of diversion, so that the conditions in this respect are different from what they were in 1861. The conditions, on the other hand, were found to be such that the board found it necessary to make an investigation to determine how great an improvement of the river could be effected by the expenditure of \$20,000 and whether the probable result to be obtained would warrant the expenditure proposed.

The investigations indicated that with a higher flow than often occurs during July and August it was not probable that the water at Farm Bridge and Island would stand more than two feet two inches above the level of the flashboards of the dam at North Billerica, unless water was being drawn from the dams of the Boston waterworks into the river below in addition to the small amount which the city of Boston is required to let run in the river. With the flow of water which makes the height of the water at Farm bridge two feet two inches above the level of the top of the flashboards, the depth of the water flowing over the flashboards in the morning was not more than five inches; consequently, the height of the water at Farm bridge with this amount of water flowing was only one foot nine inches above the level of the water in the millpond just above the dam. As no stream will flow unless the water has a slope, it was obvious that the most extended improvement of the river which could be made without lowering the water at the dam would lower the water at Farm bridge less than one foot nine

The first bars upon the stream above North Billerica begin about eighteen hundred feet from the dam, where there is a narrow rocky channel extending for a distance of five hundred feet up-stream. About four hundred feet above its upper end and about half a mile from the dam is the Fordway bar, which extends for a distance of seven hundred feet up-stream. About six hundred feet above the Fordway bar is Pollard's bar, which is about half as long as the Fordway bar and at a considerably lower level. The total fall over these bars in the morning when the water was flowing over the flashboards at the dam was found to be only about three inches, and any improvement which could be made at these bars with the sum which would be available would have been sufficient to lower the water only a very small amount at this place unless there was also a lowering of the dam.

In the course of the investigations it was learned that during the summer season the quantity of water which can be utilized in daytime at the dam is limited by the obstruction caused by the Fordway bar and the narrow rocky channel below it. Owing to these obstructions the mills cannot use in the daytime the full flow of the river during the twenty-four hours, for a portion of it runs to waste over the flashboards at night. If these obstructions should be partially or wholly removed, the mills could use a greater proportion of the total flow of the river and the water power would be benefited thereby. There was some question, therefore, whether in view of this benefit the mill owners might not be willing to lower their flashboards by an amount dependent upon the improvement of the channels, and in case such an arrangement had been made the river above the Fordway bar would have received the full benefit of the lowering of the flashboards and a slight additional lowering due to the greater capacity of the channel through the bar; but the bars in the vicinity were found to be composed of hard material which would have been expensive to move and would have limited the improvement in the rest of the river to such a degree that a satisfactory and permanent improvement of the channel above could not have been made with the amount of money available; and in view of all the circumstances the conclusion was reached that the money could best be spent in dredging the bars in the river farther up.

Several plans were considered, one of which provided for cutting a channel thirty feet wide on the bottom through the bars in Concord below the Assabet River, and twenty feet wide on the bottom through the bars above the Assabet, as far as the bar just above Farm bridge. The bottoms of these channels were to be five feet below the water level after the improvement had been completed; but it was not proposed to make any channel through a few bars where the depth was about four feet, as the depth of water over these bars was so great that they did not obstruct the flow of the water in more than a slight degree. A depth of five feet was decided upon to prevent the future obstruction of the channel by weeds.

ovement proposed, it was estimated, would make no change in the water below Barrett's bar in Concord. Above this point be a reduction in the height of the water of five inches at the the Sudbury and Assabet rivers, nearly six inches from a point ars in Concord to a point just below Robbins' bar, seven inches Robbins' bar, and ten and one-half inches at Farm bridge. ants were estimated upon the basis of a fairly high summer is unusual in July and August, though it is exceeded in wet

int of lowering of the river that could be obtained was so small deciding to enter upon the work the Board consulted with the ners, who were to pay half the cost, as to whether this amount ; of the surface of the river was sufficient in their opinion to expenditure. A meeting was held July 26, 1894, and the mated to the meadow owners by the Board. The meadow owners, g the opinion of the Board as to the amount of improvement that omplished by the proposed plan, held a meeting and subsequently e Board that it was their earnest desire that the plan be car-proposed. Upon the meadow owners expressing a desire that ould be done as proposed, the Board at once prepared plans and for proposals for the excavation of the proposed channels, and a s awarded August 30, 1894, for the excavation of the various rate of  $33\frac{1}{2}$  cents per cubic yard. The contractor, however, urchase satisfactory sureties, bids were again asked for and the bsequently awarded to the Eastern Dredging Company, who s at the time the contract was previously awarded and were now idders, at 48 cents per cubic yard. The contract was made 22, 1894, the contractors agreeing to complete the work by De- 895. The time required for the preparation and transportation y to Concord to begin the work was such that owing to the late- season the beginning of the work was postponed until the spring en the dredging in the stream was begun April 4. The work was from this time until the twenty-first of December, and the all the bars up to the canal bridge in Wayland was completed. e bars dredged, with the total number of cubic yards removed is given in the following table :—

to payment has been made for dredging done in the month of  
r after the date fixed in the contract for the termination of the

aterial dredged has been disposed of generally by dumping it into  
at places where it is wide and deep ; but material taken from the  
bar and much of that from the Canal bar was deposited upon the  
f the meadows near the river.

remain to be dredged between 3,000 and 4,000 yards in order to com-  
work as planned, and I estimate that if the amount unexpended is re-  
sted there will still be needed an additional appropriation of \$1,000.  
ging of a portion of the Canal bar under the Canal bridge will  
e omitted unless the bridge is removed, because any movement of  
under or near the bridge would be likely to cause it to collapse.

Respectfully submitted,

X. H. GOODNOUGH,

*Acting Chief Engineer.*

## THE VITAL STATISTICS OF MASSACHUSETTS FOR 1894.

---

In the last report of the Board the subject of the vital statistics of the population was treated with greater fulness of detail than had been devoted to this subject in previous reports in consequence of the increasing demand for information of this character, as well as on account of the fact that vital statistics form the basis upon which a very large share of sanitary science is founded.

In the present summary a similar method of treating the subject will be employed with that which was followed in presenting the tables for 1893, some of the longer tables being omitted.

### POPULATION.

Since the population forms the standard or basis of comparison in statements of vital statistics a brief statement of the population will be presented in the following summary:—

The census of Massachusetts is taken every five years, that of 1870, 1880, 1890, etc., by the general government, and that of the intervening periods, 1885, 1895, etc., by the State.

The present summary of the vital statistics of 1894, although relating to a year previous to the taking of the State census, has the advantage of the census of 1895 as a basis of comparison, since greater accuracy is secured by estimating the population in a year intervening between two census years than in estimating that of a year following a census year, the population at a future census being unknown.

The population of Massachusetts in 1890 was 2,238,943, and that of 1895 was 2,500,183, the rate of increase (geometric) between the census years having been a little over 2.23 per cent. annually. Of the total population of 2,500,183 in 1895 1,214,701 were males and 1,285,482 were females.

The following table presents the summary of the census and estimated populations of the State from 1842 to 1895, together with the numbers of marriages, births and deaths in each year up to and including 1894.

The marriage, birth and death rates for the same years are also given, together with the excess of births over deaths in each year.

TABLE 1. — *Marriages, Births and Deaths in Massachusetts (1842-1894), with Population and Rates per 1,000 Living.*

| YEARS.              | Population. | Marriages. | Births. | Deaths. | Excess of Births over Deaths. | Persons Married to 1,000. | Births to 1,000 Persons. | Deaths to 1,000 Persons. | Excess Rate of Births over Deaths. |

\* The statistics of the first eight years of registration are for the years ending with April 30 of each year.

† The second line of statistics for 1848 is for the eight months ending Dec. 31, 1848.

‡ The statistics for 1849 and for each of the following years are for the calendar years ending Dec. 31.

estimates of inter-censal years in the table on the foregoing are made in accordance with the rule recommended by Dr. (the geometric rate of increase).

the vital statistics of the first seven years of registration (1842-48), as well as the returns of marriages for 1849, must be regarded as generally defective; many of the returns from Suffolk County for this period are wanting, together with those of some of the small towns.

From the year 1849 onward the omissions probably constitute but a small percentage only of the total registration.

The figures for the population of census years are given in bold

#### INTERSTATE AND INTERNATIONAL VITAL STATISTICS.

The following table presents briefly the marriage, birth and death statistics of the New England States for a period of twenty years, or as long a time as they were accessible.

The statistics of the principal European countries are also presented, the data from this portion of the table being mostly obtained from the report of the registrar general of England for 1894.

TABLE 2. — *Summary of the Vital Statistics of Principal Countries for Twenty Years, and for 1893 and 1894, together with those of the New England States.*

| STATES AND COUNTRIES.        | TWENTY YEARS—1871-1890. |             |             |                                       | 1893.          |             |             |                                       | 1894.          |             |             |                                       |
|------------------------------|-------------------------|-------------|-------------|---------------------------------------|----------------|-------------|-------------|---------------------------------------|----------------|-------------|-------------|---------------------------------------|
|                              | Marriage Rate.          | Birth Rate. | Death Rate. | Excess of Birth Rate over Death Rate. | Marriage Rate. | Birth Rate. | Death Rate. | Excess of Birth Rate over Death Rate. | Marriage Rate. | Birth Rate. | Death Rate. | Excess of Birth Rate over Death Rate. |

# MARRIAGES.

The whole number of marriages registered in Massachusetts in 1890 was 20,619. This number was equivalent to a rate of 16.86 per 1,000 of the estimated population (persons married), or 8.43 marriages in each thousand. It was also equivalent to one marriage for each 119 persons.

The number of marriages was less by 2,195 than those of 1893. The marriages and marriage rates for the ten years (1885-94) are as follows:—

TABLE 3.—*Marriages and Marriage Rates, 1885-94.*

| YEARS. | Marriages. | Marriage Rates. |
|--------|------------|-----------------|
| 1885   | 17,052     | 17.6            |
| 1886   | 18,018     | 18.0            |
| 1887   | 19,533     | 19.0            |
| 1888   | 19,739     | 18.7            |
| 1889   | 20,397     | 18.7            |
| 1890   | 20,838     | 18.6            |
| 1891   | 21,675     | 18.8            |
| 1892   | 22,507     | 20.0            |
| 1893   | 22,814     | 18.7            |
| 1894   | 20,619     | 16.9            |
| Total, | 203,192    | —               |
| Mean,  | —          | 18.5            |

The marriage rate was less than that of any year since 1879. The rate of the ten-year period (1885-94) was 18.5.

*Marriages by Counties.*—The number of marriages in each county during the four years, 1891, 1892, 1893 and 1894, together with the marriage rates for 1890, were as follows:—

TABLE 4. — *Marriages by Counties, 1891-94, and Marriage Rates, 1890.*

is column the inaccuracies due to the unequal lengths of the months are eliminated by the daily number of marriages in each month and comparing this number with a daily of 100 for the whole year.

mean daily number of marriages for the year was 56.5.

greatest daily number of marriages occurred in June, October November, and the least in March, February and August.

percentages of marriages in each quarter were as follows: quarter 18.31 per cent., second quarter 27.67, third quarter fourth quarter 30.54.

### BIRTHS.

whole number of living births registered in Massachusetts in 1894 was 66,936, which was larger than that of any previous year since the beginning of registration. The birth rate was 27.4 per cent. of the estimated living population, which was less than that of 1891, 1892 or 1893, but greater than that of any previous year since 1874.

births and birth rates for the ten years 1885–94 were as follows:—

TABLE 7.—*Births and Birth Rates, Ten Years, 1885–94.*

| YEARS. | Births. | Birth Rates. | YEARS.      | Births. | Birth Rates. |
|--------|---------|--------------|-------------|---------|--------------|
| . . .  | 48,790  | 25.1         | 1892, . . . | 65,824  | 28.1         |
| . . .  | 50,788  | 25.4         | 1893, . . . | 67,192  | 28.1         |
| . . .  | 53,174  | 25.9         | 1894, . . . | 66,936  | 27.4         |

| . . .  | 57,777  | 25.8         |             |         |              |
| . . .  | 63,004  | 27.5         | Mean, . .   | —       | 26.6         |

*Sex.*—Of the whole number of living children born in 1894, 34,338 were males and 32,575 were females, indicating a ratio of 1,054 males to 1,000 females, that of the period of forty-two years (1853-94) having been 1,055 males to 1,000 females.

The following were the numbers by sexes for the four years 1891-94 and for the forty-two years 1853-94:—

TABLE 8.—*Births by Sexes, 1853-94, 1891, 1892, 1893 and 1894.*

| YEARS.             | Males.  | Females. | Males to 1,000 Females. |
|--------------------|---------|----------|-------------------------|
| 1853-94, . . . . . | 920,067 | 871,781  | 1,055                   |
| 1891, . . . . .    | 32,532  | 30,434   | 1,069                   |
| 1892, . . . . .    | 33,758  | 31,951   | 1,057                   |
| 1893, . . . . .    | 34,328  | 32,829   | 1,046                   |
| 1894, . . . . .    | 34,338  | 32,575   | 1,054                   |

The ratio of male to female births in England for the fifty-seven years ending with 1894 was 1,042 males to 1,000 females.

*Seasons.*—The number of births in each month and the monthly ratio reduced to a standard of 100 was as follows:—

TABLE 9.—*Births by Months (1894).*

| MONTHS.              | Births. | Monthly Ratio reduced to a Standard of 100. | MONTHS.             | Births. | Monthly Ratio reduced to a Standard of 100. |
|----------------------|---------|---------------------------------------------|---------------------|---------|---------------------------------------------|
| January, . . . . .   | 5,500   | 96.7                                        | October, . . . . .  | 5,530   | 97.3                                        |
| February, . . . . .  | 4,978   | 96.9                                        | November, . . . . . | 5,579   | 101.4                                       |
| March, . . . . .     | 5,681   | 99.9                                        | December, . . . . . | 5,907   | 103.9                                       |
| April, . . . . .     | 5,529   | 100.5                                       | Unknown, . . . . .  | 3       | —                                           |
| May, . . . . .       | 5,472   | 96.2                                        | Total, . . . . .    | 66,936  | —                                           |
| June, . . . . .      | 5,506   | 100.1                                       | Mean, . . . . .     | —       | 100.0                                       |
| July, . . . . .      | 5,999   | 105.5                                       |                     |         |                                             |
| August, . . . . .    | 5,794   | 101.9                                       |                     |         |                                             |
| September, . . . . . | 5,458   | 99.2                                        |                     |         |                                             |

The mean daily number of births was 183.4, and from the foregoing table it appears that the highest daily number of births occurred in July and December, and the least in May and January.

The highest quarterly percentage of births registered was in the third quarter of the year, and the same may be said of the births in each year of the previous twenty-year period, except 1878, in which the greatest number was in the fourth quarter.

*Births by Counties.* — The numbers of living births in each county during the four years 1891, 1892, 1893 and 1894, together with the birth rates for 1890, were as follows: —

TABLE 10. — *Births by Counties, 1891-94, and Birth Rates, 1890.*

The illegitimate birth rates of 1893 and 1894 are estimated for the whole State, except the City of Boston.

TABLE 12 — *Illegitimate Births by Counties (1891, 1892, 1893 and 1894).*

| THE STATE.      | Barnstable. | Berkshire. | Bristol. | Dukes. | Essex. | Franklin. | Hampden. | Hampshire. | Middlesex. | Nantucket. | Norfolk. | Plymouth. | Suffolk. | Worcester. |
|-----------------|-------------|------------|----------|--------|--------|-----------|----------|------------|------------|------------|----------|-----------|----------|------------|
| 1891, . . . . . | 11          | 21         | 50       | —      | 79     | 5         | 44       | 7          | 121        | 1          | 22       | 14        | 654      | 49         |
| 1892, . . . . . | 8           | 27         | 65       | 3      | 81     | 10        | 62       | 12         | 171        | 3          | 21       | 13        | 445      | 69         |
| 1893, . . . . . | 10          | 26         | 59       | 1      | 94     | 10        | 46       | 8          | 149        | 2          | 23       | 11        | 14       | 87         |
| 1894, . . . . . | 6           | 33         | 53       | 1      | 100    | 7         | 52       | 22         | 168        | 2          | 25       | 15        | 14       | 66         |

In the foregoing table are presented the statistics of illegitimate births by counties for the four years ending with 1894. The special point worthy of note in this table is the apparently defective record of Suffolk County for the years 1893 and 1894.

*Plural Births.*—In 1894 there were registered 654 cases of plural births, being in the ratio of 9.8 per 1,000 births. The number of children born was 1,316, of which number 1,292 were twins and 24 were triplets. Of the whole number, 658 were males and 657 were females.

The statistics for the four years 1891, 1892, 1893 and 1894 were as follows :—

TABLE 13.

| YEARS.                          | Cases of Twins. | Cases of Triplets. | Cases of Quad-ruplets. | Numbers of Living Births to one Case of Twins. | Number of Living Births to one Case of Triplets. |

| Mean, . . . . .                 | —               | —                  | —                      | 113                                            | 9,961                                            |

There has been a notable increase in the number and ratio of cases of triplet births in the past seven years, from 1 in 27,446 in 1888 to 1 in 8,367 in 1894.

*Still-births.*—The total number of still-births registered in 1894 was 2,353, the number for the two preceding years being 2,222 in 1892 and 2,444 in 1893.

The following are the statistics relative to the sexes of the still-born for 1894 and for the period 1853 to 1894, forty-two years :—

|                                                                             | 1894. | 1853-94. |
|-----------------------------------------------------------------------------|-------|----------|
| Total number of the still-born, . . . . .                                   | 2,353 | 55,788   |
| Males, . . . . .                                                            | 1,424 | 30,941   |
| Females, . . . . .                                                          | 854   | 20,768   |
| Not stated, . . . . .                                                       | 75    | 4,079    |
| Ratio of males to 1,000 females, among those whose sex was known, . . . . . | 1,667 | 1,490    |

## DEATHS.

mortality statistics surpass all other vital statistics in importance, whether they are considered from a social, an actuarial or a sanitary standpoint." — NEWSHOLME.

The number of deaths registered in 1894 was 46,791; this was more than those of either 1892 or 1893, but greater than those of the previous years.

The death rate per 1,000 of the estimated living population was 19.70, that of the decade ending with 1894 having been 19.70.

The following are the deaths and death rates for the ten-year period 1885-94:—

TABLE 14.

| YEARS. | Deaths. | Death Rates. | YEARS.       | Deaths. | Death Rates. |
|--------|---------|--------------|--------------|---------|--------------|
| . . .  | 38,094  | 19.6         | 1892, . . .  | 48,762  | 20.8         |
| . . .  | 37,244  | 18.6         | 1893, . . .  | 49,084  | 20.5         |
| . . .  | 40,763  | 19.8         | 1894, . . .  | 46,791  | 19.1         |
| . . .  | 42,097  | 19.9         |              |         |              |
| . . .  | 41,777  | 19.2         | Total, . . . | 433,325 | —            |
| . . .  | 43,528  | 19.4         | Mean, . . .  | —       | 19.70        |
| . . .  | 45,185  | 19.7         |              |         |              |

*Deaths by Sexes.*—The number of deaths of males recorded in 1894 was 23,788 and that of females was 23,003. Estimating the proportion of the sexes upon the same basis as in 1890, the death rates of the sexes were 20.02 per 1,000 for males and 18.29 for females.

TABLE 15. — *Mortality of the Sexes, Census Years and 1894.*

| YEARS. | Deaths of Males. | Deaths of Females. | Death Rate of Males. | Death Rate of Females. | Deaths of Males to 1,000 Deaths of Females in Equal Numbers Living. |
|--------|------------------|--------------------|----------------------|------------------------|---------------------------------------------------------------------|
| . . .  | 11,444           | 11,547             | 19.3                 | 18.4                   | 1,048                                                               |
| . . .  | 13,085           | 13,024             | 21.7                 | 19.6                   | 1,107                                                               |
| . . .  | 13,699           | 13,598             | 19.5                 | 18.6                   | 1,048                                                               |
| . . .  | 17,329           | 17,619             | 21.8                 | 20.5                   | 1,063                                                               |
| . . .  | 17,426           | 17,852             | 20.3                 | 19.3                   | 1,052                                                               |
| . . .  | 18,889           | 19,205             | 20.2                 | 19.0                   | 1,063                                                               |
| . . .  | 21,767           | 21,761             | 20.0                 | 18.9                   | 1,058                                                               |
| . . .  | 23,788           | 23,003             | 20.0*                | 18.3*                  | 1,094*                                                              |

\* Estimated.

The disparity between the death rates of the sexes in Massachusetts was generally less than that of England, which was as 1,121 deaths of males to 1,000 deaths of females in equal numbers living for 1894, and as 1,103 to 1,000 for the whole period of registration (1838-94).

*Deaths by Seasons.*—In the following table are presented the statistics of deaths in Massachusetts by months and by sexes. For the purpose of presenting the seasonal mortality as fully and as clearly as possible, the method employed by Dr. Böckh of Berlin in his “Jahrbuch” has been followed. The exceedingly accurate and careful statistical methods adopted in Berlin give to the mortality statistics of that city a value which cannot be attained here under present American modes of collection of statistics. The figures in the following table may be taken as approximately correct, any errors that may exist being probably limited to the decimals only in columns 4, 5 and 6.

TABLE 16. — *Mortality by Months, Massachusetts (1894).*

| August, . . .    | 2,254       | 2,317         | 4,571        | 21.9                                       | 115.1                                                      | 147.5                   |
| September, . . . | 2,136       | 2,008         | 4,144        | 20.5                                       | 107.7                                                      | 138.1                   |
| October, . . .   | 1,872       | 1,831         | 3,703        | 17.6                                       | 93.2                                                       | 119.5                   |
| November, . . .  | 1,729       | 1,650         | 3,379        | 16.6                                       | 87.8                                                       | 112.6                   |
| December, . . .  | 1,868       | 1,775         | 3,643        | 17.3                                       | 91.6                                                       | 117.5                   |
|                  | 23,788      | 23,003        | 46,791       | 19.1                                       | 100.0                                                      | 128.2                   |

In the foregoing table, in the figures presented in columns 4 and 5 the inaccuracies due to the unequal length of the months have been eliminated by comparing the daily number of deaths in each month with the mean daily number for the year. In estimating the mortality rates given in column 4, a quarterly estimate has been adopted, based upon the rate of growth from 1890 to 1895, after the manner adopted by the registrar general of England in his weekly reports. By this table it appears that the months in which

test daily number of deaths occurred were July, August  
ary, and those which had the least were June, November

percentages of deaths in each quarter of the year were as

|                           |             |
|---------------------------|-------------|
| first quarter, . . . . .  | 25.6        |

| 1893, . . . . .                      | 36.53                         | 39.24                                   | 98.10                      | 19.78                                   | 9.25                              |
| 1894, . . . . .                      | 35.93                         | 37.94                                   | 88.47                      | 18.39                                   | 8.64                              |
| 1890-94 (Mean, five years, 1890-94), | 36.83                         | 39.50                                   | 92.68                      | 19.66                                   | 8.61                              |

\* Still-births excluded.

By this table it appears that very marked changes have taken place in the groups marked I., II. and III., the first two having notably decreased, while the third has quite as notably increased.

The following table presents the mortality from the ten most prominent causes of death in Massachusetts for the ten years 1885 to 1894, in the order of their prominence:—

TABLE 19.— *Mortality from Ten Prominent Causes. — 1885-1894.*

| CAUSES OF DEATH.        | Deaths,<br>1894. | 1885. | 1886. | 1887. | 1888. | 1889. | 1890. | 1891. | 1892. | 1893. | 1894. |

| Diphtheria and croup, . | 1,801            | 6     | 10    | 9     | 10    | 5     | 6     | 7     | 7     | 7     | 7     |
| Kidney diseases, . .    | 1,788            | 7     | 8     | 8     | 8     | 9     | 9     | 9     | 10    | 8     | 9     |
| Old age, . . . . .      | 1,669            | 8     | 6     | 6     | 6     | 7     | 7     | 6     | 6     | 6     | 5     |
| Bronchitis, . . . .     | 1,572            | 9     | 7     | 7     | 7     | 10    | 10    | 8     | 8     | 10    | 8     |
| Cancer, . . . . .       | 1,568            | 10    | 9     | 10    | 9     | 8     | 8     | 10    | 9     | 9     | 10    |

\* Including deaths certified as from apoplexy, paralysis, insanity, inflammatory diseases of the brain, and its membranes, and other brain diseases.

om this table it appears that consumption has maintained its ion at the head of the list for the whole decade, although very ly approached by pneumonia in 1893. Brain diseases held the id place from 1835 to 1892, but, for the year 1893, was dis- d by pneumonia. Diphtheria and croup attained the seventh for the first four years, and then rose to the fifth, but fell to ast place in 1891 and 1893, rising again to the sixth place in . Heart diseases and cholera infantum maintained, respectively, outh and fifth places for nearly the whole period.

*istics of Certain Causes and Groups of Causes of Death, Massa- chusetts, 1894.*

Table 20 are presented the principal statistics relative to the wing causes of death : —

|                       |                  |
|-----------------------|------------------|
| Small-pox.            | Pneumonia.       |
| Measles.              | Whooping-cough.  |
| Scarlet fever.        | Cancer.          |
| Diphtheria and croup. | Kidney diseases. |
| Typhoid fever.        | Heart diseases.  |
| Cholera infantum.     | Brain diseases.  |
| Consumption.          |                  |

data presented are the following : —  
er of deaths from each of the foregoing causes in each year for  
venty years (1875-94), . . . . .  
rate from each of the same causes per 10,000 of the living popu-  
ation for each year, . . . . .  
stage of the total mortality for each year, . . . . .  
xtals and means for the twenty-year period, . . . . .

*Statistics of Certain Causes and Groups of Causes of Death for  
Twenty Years in Massachusetts (1875-94).*

Table 20 presents the statistics of certain destructive infectious and other diseases for a period of twenty years (1875-94), embracing the number of deaths, the death rate per 10,000 of the living population and the percentage of the total mortality for each year.

*Small-pox.*—The total number of deaths from this cause in 1894 was 33, a number greater than that of any year since 1882. It represented a death rate from this cause of .13 per 10,000 living and a percentage of .07 of the mortality from all causes.

*Measles.*—The deaths from measles was 98, or 178 less than those of the previous year and also less than those of any previous year since 1884, except 1892, when it was 88. The ratio of the living population was .4 and the percentage of the total mortality .21.

*Scarlet Fever.*—The deaths from scarlet fever were 649, which was less than those of either 1892 or 1893, but greater than those of any other previous years since 1876. The death rate from this cause was 2.6 per 10,000 of the living population and the percentage of the total mortality was 1.39.

*Diphtheria and Croup.*—The deaths from diphtheria and croup were 1,801, which was considerably greater than that of either of the four years 1890-93. The death rate per 10,000 living was 7.4 and the percentage of the total mortality was 3.85, both of which were less than the mean ratios for the twenty-year period (1875-94.)

*Typhoid Fever.*—The deaths from typhoid fever were 748, or less than those of any previous year since 1879. The ratio of the living population was 3.1 per 10,000 and the percentage of the total deaths was 1.6. Each of these ratios was less than the mean of the twenty-year period.

*Cholera Infantum.*—The number of deaths from this cause was 2,676. The death rate per 10,000 of the living population was 10.9 and the percentage of the total mortality 5.7. Each of these ratios being nearly identical with the mean for the twenty-year period.

*Consumption.*—The number of deaths from consumption was 5,463, or less than that of any year of the twenty-year period since 1879. The death rate per 10,000 of the living population and the percentage of the total deaths were each considerably less than

mean of the twenty-year period, and each of these ratios has usually diminished during the period.' (For fuller information relative to the mortality from this cause see last annual report.)

*Pneumonia*.—The deaths from this cause were 4,101. The ratio 10,000 living was 16.7 and the percentage of the total deaths 1.93, these ratios differing but little from the mean ratios of the twenty-year period.

*Whooping-cough*.—The deaths from whooping-cough in 1894 were 435. In absolute numbers, this mortality was greater than that of any year of the twenty-year period, but relatively it was exceeded the mortality from this cause in 1877, 1878 and 1884. The death rate per 10,000 living was 1.8 and the percentage of the total mortality was .93, the means of the twenty-year period being 1.8 and .93.

*Cancer*.—The deaths from cancer were 1,568, which number was greater than that of any previous year of the twenty-year period.

The death rate per 10,000 of the population was 6.4 as compared with a mean of 5.5 for the twenty years, and the percentage of the total mortality was 3.35, as compared with a mean of 2.79. The decrease in mortality from this cause was not so rapid during the last years as during the first half of the period.

*Kidney Diseases*.—The deaths from this group of causes were 211, which was greater than that of any year in the twenty-year period from the same causes. The death rate per 10,000 of living population was 7.0, as compared with a mean of 5.2, and the percentage of the total mortality was 3.68, as compared with a mean of 3.68.

*Heart Diseases*.—The deaths from this group of causes were 3,432, which number was less, absolutely, than that of either of the three preceding years. The death rate per 10,000 living was 14.0, as compared with a mean of 12.1, and was also less than that of either of the preceding six years. The percentage of the total mortality was 6.19, as compared with a mean of 6.19.

*Brain Diseases*.—The deaths from this group of causes in 1894 (including those from apoplexy, paralysis, cephalitis, insanity, softening of the brain and other brain diseases) were 4,995, which was less than those of either of the three preceding years. The death rate per 10,000 living from these causes was 20.4, as compared with a mean of 18.4 for the twenty-year period, and the percentage of the total

mortality was 10.7, as compared with 9.7 for the twenty-year period.

*Erysipelas.* — The deaths from this cause were 157, as compared with 251 in 1893.

*Puerperal Fever.* — The deaths from puerperal fever were 49, as compared with 46 in 1893. The deaths from other incidents of childbirth were 216.

*Malarial Fevers.* — The deaths registered as from these causes were 73.

*Syphilis.* — The deaths registered as from syphilis were 64, of which 37, or more than half, occurred in Suffolk County.

There were no deaths from hydrophobia, glanders, anthrax or trichinosis.

#### *Medical Examiner Returns.*

Separate returns of all deaths investigated by medical examiners are required by law. These comprise deaths by homicide, suicide, accidents and many deaths of a sudden or suspicious character which are referred to the medical examiners for investigation.

Of this class of deaths the whole number investigated in 1894 was 2,159, of which number 1,649 were deaths of males, 505 were deaths of females and the sex of 5 was unknown. The ratio of deaths of this class among males and females has shown but little change in the past ten years.

The whole number investigated was less than those of either 1892 or 1893, which were, respectively, 2,209 and 2,221. The mean annual number of deaths of this class investigated in the five-year period 1885-89 was 1,503, while that of the succeeding five-year period (1890-94) was 2,040, indicating a relative increase from 7.3 deaths per 10,000 of the living population investigated in the first period to 8.7 deaths per 10,000 in the second period.

*Homicide.* — The deaths from homicide were 68, as compared with 72 and 76, respectively, in 1892 and 1893. Comparing the two five-year periods 1885-89 and 1890-94 there was a slight increase, from an annual mean of .24 per 10,000 of the population in the former period to .27 per 10,000 in the latter.

*Suicide.* — The deaths from suicide were 270, while those of 1892 and 1893 were, respectively, 273 and 290. Comparing the two five-year periods, there was an increase from .87 per 10,000 of the living population in the former to 1.04 per 10,000 in the latter.

*Accident.*—The deaths from accident investigated were 975, as compared with 974 and 976 in 1892 and 1893. The mean annual ratio of deaths from accident investigated had also increased from 3.47 per 10,000 in the former to 3.97 in the latter period.

*Deaths from Natural and Unknown Causes.*—The deaths of this class investigated were 846, as compared with 890 in 1892 and 879 in 1893, while the mean annual ratio had increased from 2.72 per 10,000 in the former to 3.43 in the latter five-year period.

## WATER SUPPLY AND SEWERAGE.\*

---

ort required by the provisions of chapter 375 of the Acts of 1888, entitled in Act to protect the purity of inland waters, and to require consultation with the State Board of Health regarding the establishment of systems of water supply, drainage and sewerage.”]

he following report contains a summary of the work of the State Board of Health during the year 1895, under the provisions of chapter 375 of the Acts of 1888, including the substance of the replies given by the Board to those cities, towns, corporations and individuals which have applied to the Board for its advice relative to systems of water supply, drainage and sewerage, under the requirements of this act, together with a brief statement of the work done at the experiment station at Lawrence and in connection with the investigations of water supplies and rivers.

uring the year 1895 public water supplies were introduced in the towns of Barre, Longmeadow, Millbury, Monson and Rockport, and important additions to the sources of many existing works were made. At the end of the year 1895 all of the 31 cities in the Commonwealth and 123 towns out of a total of 322 were provided with a public water supply. The total population of the communities having a public water supply is 89.5 per cent. of the total population of the State. There are now but 4 towns which by the census of 1895 have a population exceeding 3,500 which are not provided with a public water supply. The names of these towns, with their respective populations, are as follows:—

|                               |                   |
|-------------------------------|-------------------|
| Town of Barnstable, . . . . . | Population, 4,055 |
| of North Andover, . . . . .   | “ 3,569           |
| of Blackstone, . . . . .      | “ 6,089           |
| of Winchendon, . . . . .      | “ 4,490           |

---

The first pages of this report were contained in a report made to the Legislature Jan. 6, 1896 (see Document, No. 4). A portion of the report then made, relating to the work done at the Law-Experiment Station, is not reproduced, because a more complete account of the work done at this will be found in a subsequent part of this volume.

The rapid growth in the number of water supplies in the State in twenty years is indicated by a comparison of the statistics for 1895 with similar ones for 1875. At the end of the latter year 15 cities out of a total of 19 and 35 towns out of a total of 323 were provided with public water supplies, and the communities supplied contained 48.3 per cent. of the total population of the State.

The tendency in recent years toward municipal control of water supplies is indicated by a comparison of the number and population of municipalities supplied by private companies at the end of 1895 with the number similarly supplied at the end of 1890. At the end of 1895 all of the cities and 77 of the 123 towns in the State having a public water supply owned their works, while 46 towns were supplied by private companies. The total population of places supplied by private companies was 212,579, or 9.5 per cent. of the total population supplied. At the end of 1890 five of the 28 cities in the State having public water supplies and 50 of the 109 towns were supplied by private companies. The total population supplied from private works in 1890 was 318,319 or 16 per cent. of the total population supplied. There has been an increase of 17 in the number of works since 1890.

The flow of streams, as indicated by that of the Sudbury River, was less than the normal in January, February, March, May, June, August and September, slightly in excess of the normal in April and July, and very greatly in excess in the months of October, November and December, the average flow for November being the highest recorded in that month on the Sudbury for twenty-one years. The result of this distribution of the flow upon sources of water supply was to cause many of the large ponds having comparatively small water-sheds to fail to fill in the spring; but, owing to the early and heavy rainfall in the fall, the drought was not felt so seriously as has been the case in other years. The very low flow of streams in September and the early portion of October was severely felt by those communities supplied from small reservoirs having comparatively large water-sheds, which depend largely upon the daily flow of the streams to prevent a shortage of water.

The chemical analyses of the water supplies and rivers of the State have been continued during the year, 2,250 samples having been examined. The following is a classified list of the waters examined during the year:—

**TABLE I.**

|                                                                                                       |              |
|-------------------------------------------------------------------------------------------------------|--------------|
| From open and covered reservoirs for the storage of ground waters,                                    | 46           |
| From ground-water supplies,                                                                           | 393          |
| Special investigations of regular water supplies affected by tastes, odors, etc.,                     | 19           |
| From ponds and storage reservoirs and their inlets,                                                   | 815          |
| From streams and miscellaneous sources,                                                               | 100          |
| <b>Total from regular water supplies,</b>                                                             | <b>1,373</b> |
| On connection with investigations of new sources of water supply,                                     | 295          |
| With reference to pollution of streams,                                                               | 287          |
| With reference to sewage purification at Worcester, Framingham, Marlborough, Gardner, Medfield, etc., | 246          |
| On connection with the study of epidemics,                                                            | 7            |
| Miscellaneous,                                                                                        | 42           |
|                                                                                                       | <b>877</b>   |
| <b>Total,</b>                                                                                         | <b>2,250</b> |

The examination of the microscopic organisms has also been continued in the waters which have been examined chemically, and those which are found in large numbers in any water at times when there is complaint of its taste or odor have been studied with special attention, with a view to learning the conditions necessary to their existence and development.

With the rapid extension of water-supply systems throughout the State and the constant increase in the use of water has come not only recognition of the necessity that the supply shall be ample in quantity at all times, and free from danger of contamination by animal refuse or other poisonous matter, but also an appreciation of the importance of excellence in other respects; and the possession by a community of a water that is at all times soft, free from taste or odor and of attractive appearance, has a certain commercial value as well, compared with less attractive supplies.

Of the supplies in the State drawn from natural ponds, some have from time to time been affected by the presence of microscopic organisms in such numbers as to cause the waters to become offensive to taste and smell to such a degree in some instances as to lead to the consideration of measures for obtaining a satisfactory supply from another source, at least during times when the water of the present source is unfit for use. The periodic occurrence of such conditions in ponds, which at other times may furnish a water of satisfactory

quality, indicates the necessity of thorough investigation of a source before the construction of works for supplying a community with its water is undertaken.

Investigations as to the quality of water of artificial storage reservoirs, both of those which have been thoroughly prepared for the purpose by the removal of all soil and vegetable matter from the area flowed, and of those where the preparation has been insufficient or where no preparation at all beyond a simple clearing of the area has been made, have shown that, while water often deteriorates greatly in quality when stored in reservoirs of the latter class, on the other hand, the quality of the water is not only unlikely to deteriorate, but is likely to improve by storage in reservoirs thoroughly prepared for the purpose, the degree of improvement depending chiefly on the character of the water as it enters the reservoir and the length of time that it is allowed to remain there.

The occurrence of excessive amounts of iron in ground waters has frequently been referred to in previous reports. Information obtained from systematic examinations of existing sources and from investigations of proposed new supplies has shown that the quality of the water taken from single test wells, from which comparatively little water has previously been drawn, frequently does not furnish a reliable indication as to the probable quality of the ground water of a locality after the comparatively large quantity used by a town or village has been drawn from the ground in the vicinity for a considerable length of time. A satisfactory knowledge on these points can often be obtained only from long-continued pumping from such sources under circumstances which would most readily allow of the development of unfavorable conditions affecting the quality of the water. Such pumping tests, when accompanied with careful observations, are usually valuable in the indications that they may furnish of the probable capacity of a ground-water source.

As a result of its investigations, the Board has frequently called attention to the danger in the use for domestic purposes of water taken directly from running streams exposed to pollution by inhabitants upon their water-sheds; and a marked decrease in the use of such sources has been noted, several communities going to the expense of entirely new sources of supply, to avoid the use of water from polluted streams.

Observations of the operation of the Lawrence city filter have been continued through the year, and a summary of the results of chemical

bacterial analyses of samples of water before and after filtration given in subsequent pages. The following table, which is the result of a careful investigation, shows the total number of deaths from typhoid fever in Lawrence and the deaths from this cause per 100 inhabitants for the year 1895 and the ten previous years:—

TABLE II.

*Deaths from Typhoid Fever in Lawrence, 1885-95.*

| YEAR.     | Total Number of Deaths. | Deaths per 10,000 of Population. | PERSONS KNOWN TO HAVE BEEN EXPOSED TO INFECTION BY— |                                                                |                         |
|-----------|-------------------------|----------------------------------|-----------------------------------------------------|----------------------------------------------------------------|-------------------------|
|           |                         |                                  | Drinking Canal Water.                               | While living out of Town just before falling sick in Lawrence. | Nursing Other Patients. |
| . . . . . | 17                      | 4.2                              | -                                                   | -                                                              | -                       |
| . . . . . | 23                      | 5.75                             | -                                                   | -                                                              | -                       |
| . . . . . | 47                      | 11.75                            | -                                                   | -                                                              | -                       |
| . . . . . | 48                      | 12.                              | -                                                   | -                                                              | -                       |
| . . . . . | 55                      | 13.75                            | -                                                   | -                                                              | -                       |
| . . . . . | 60                      | 13.33                            | -                                                   | -                                                              | -                       |
| . . . . . | 55                      | 12.20                            | -                                                   | -                                                              | -                       |
| . . . . . | 50                      | 11.11                            | -                                                   | -                                                              | -                       |
| . . . . . | 39                      | 8.66                             | -                                                   | -                                                              | -                       |
| . . . . . | 24                      | 5.00                             | 12                                                  | 4                                                              | 1                       |
| . . . . . | 16                      | 3.07                             | 9                                                   | 2                                                              | -                       |

certain facts are to be noted in connection with the figures presented in the table. Investigations by the Board of the causes of the excessive death rates from typhoid fever in Lawrence in the years 1885 and 1890 pointed so strongly to the water supply as one of the important causes that the Board at the beginning of 1891 warned the citizens against its use for drinking except after thorough boiling. Supplies of water pumped directly from the canals are used for various purposes in the mills; this water is in many places easily accessible for drinking and is so used, notwithstanding that city water is also provided. The filter was first operated in September, 1891, and all of the water supplied to the city has been filtered since that time.

In connection with investigations as to the purification of sewage, a large number of samples of sewage and effluent from existing sewage disposal works has been examined. The results of these

investigations are of much value, when taken in connection with the information obtained at the Board's experiment station, in advising cities and towns with reference to the disposal of sewage.

The growth of manufacturing industries and the increase in the population of manufacturing towns and villages have tended to increase the pollution of streams, while the reduced flow of the streams in the past two dry seasons has assisted in making the effect of the pollution more noticeable. The condition of those streams most liable to serious pollution is examined from time to time by means of chemical analyses, and in some cases steps are being taken by local authorities for the removal of causes of pollution.

The subject of the treatment of manufacturing sewage has received much attention during the year, and experiments have been begun with reference to purifying refuse from tanneries, wool-washing and other establishments, drainage from which is a prime factor in the pollution of many streams and watercourses. While the experiments have not yet been carried far enough to warrant any extended statement as to the results obtained, it may be said that sufficient information has been furnished by the investigations thus far made to make it evident that manufacturing sewage may be purified sufficiently to prevent its polluting a stream, at a sufficiently moderate cost to obviate the danger of crippling the manufacturing industries.

---

### ADVICE TO CITIES AND TOWNS.

Under the provisions of chapter 375 of the Acts of 1888, entitled "An Act to protect the purity of inland waters, and to require consultation with the State Board of Health regarding the establishment of systems of water supply, drainage and sewerage," the Board is required "from time to time to *consult with and advise the authorities of cities and towns, or with corporations, firms or individuals either already having or intending to introduce systems of water supply, drainage or sewerage, as to the most appropriate source of supply, the best practicable method of assuring the purity thereof or of disposing of their drainage or sewage, having regard to the present and prospective needs and interests of other cities, towns, corporations, firms or individuals which may be affected thereby.* It shall also from time to time consult with and advise persons or corporations engaged or

nding to engage in any manufacturing or other business, drain-  
 or sewage from which may tend to cause the pollution of any  
 nd water, as to the best practicable method of preventing such  
 ution by the interception, disposal or purification of such drain-  
 or sewage: *provided*, that no person shall be compelled to bear  
 expense of such consultation or advice, or of experiments made  
 the purposes of this act. *All such authorities, corporations,*  
*ns and individuals are hereby required to give notice to said Board*  
*their intentions in the premises, and to submit for its advice outlines*  
*their proposed plans or schemes in relation to water supply and*  
*posal of drainage and sewage; and all petitions to the Legislature*  
*authority to introduce a system of water supply, drainage or sew-*  
*ge shall be accompanied by a copy of the recommendation and advice*  
*he said Board thereon."*

during the year 1895 the Board has given its advice to the follow-  
 cities, towns, corporations and individuals who have applied for  
 h advice under the provisions of the general act of 1888, or  
 ler special acts relating to water supply and sewerage.

Replies were made during the year to applications made from the  
 owing sources for advice relative to water supply: Adams (two  
 lies), Amesbury (the Powow Hill Water Company), Billerica,  
 dford, Brookfield, Cohasset, Dighton and Somerset (two replies),  
 Edgartown Water Company, Gloucester, Greenfield, Groton,  
 tfield, Haverhill, Holden, Holyoke, Kingston, Leicester, Leomin-  
 r, Lowell, Montague (Miller's Falls), Montague (Village), Paxton,  
 operell, Pittsfield, Reading, Rutland, Sheffield, Shirley, Stoughton,  
 lpole, Wenham, Westfield, Weston, Williamstown, Winchendon,  
 rentham (Plainville) and Worcester.

Replies relating to sewerage and sewage disposal were made, in  
 wer to applications from the following sources: Amesbury,  
 dover, Brockton, Fairhaven, Framingham, Springfield, Tewks-  
 y, the State Farm at Bridgewater, and Webster.

Replies were also made during the year relative to the subject of  
 lution of streams, to certain authorities and other parties in the  
 owing towns: to the board of health of Danvers, relative to the  
 lution of Crane's River; to the selectmen of Millbury, in reply  
 a communication relative to the pollution of the Blackstone  
 er by the city of Worcester; to the selectmen of Shrewsbury,  
 tive to the pollution of Lake Quinsigamond by the sewage  
 the State Lunatic Hospital at Worcester; and to the selectmen

of Northborough, in reply to a letter relative to the pollution of Lake Chauncy by the sewage of the State Lunatic Hospital at Westborough.

### WATER SUPPLY.

The following is the substance of the action of the Board during the past year, in reply to applications for advice relating to water supply : —

**ADAMS.** The committee on water supply of the Adams Fire District applied to the Board Feb. 21, 1895, for its advice relative to taking a ground-water supply from the valley of the Hoosac River, and as to the best method of supplementing its water supply. The Board replied to this application as follows : —

BOSTON, May 2, 1895.

The portion of the valley indicated by you as a possible ground-water source is in the vicinity of the Hoosac River, south of Cheshire Harbor. This locality has been examined by one of the engineers of the Board, but, as no tests have been made by driving wells or otherwise to show the character of the material beneath the surface and to obtain a sample of water for analysis, it is impracticable to advise definitely at the present time as to the probable quality and quantity of water to be obtained at this place.

A sample of water collected April 17, 1895, from a flowing tubular well in the valley of the river at Zylonite, was analyzed, and found to be so hard that it would not be of satisfactory quality for many of the purposes for which a public water supply is used ; and the same statement may be made with regard to the water supplied from the wells of the North Adams water works.

In view of these results, there is much doubt as to whether a water supply contained from the ground as proposed would be of satisfactory quality ; and this point can be definitely settled only by determining the hardness and other characteristics of a sample of water taken from the ground at the proposed location.

While, as already stated, it is impracticable to advise definitely at this time as to the probable quantity of water, it may be said that the surface indications point to a limited rather than to an ample supply.

In view of the insufficiency of the present sources of supply during the dry portion of the past year, and the uncertainty as to the best method of obtaining a supplementary supply, the Board advises you to have the whole question of the water supply of the town more thoroughly investigated, with the aid of an engineer skilled in such work.

In addition to the investigation with regard to obtaining a supplementary ground-water supply, it is desirable to ascertain the quality and quantity of

er flowing during the dry portion of the year in streams not now used, which may be available for supplying your town; and to ascertain whether it is not feasible to build a reservoir to store enough water to maintain the supply during the portions of the year when the natural flow of the streams is insufficient. It would also be well to have the quantity of water used by the town measured, with a view to determining whether the consumption of water is excessive; and, if this should be found to be the case, it might be feasible to materially reduce the consumption by preventing leakage and waste, and in this way make the consumption of water correspond more nearly with the capacity of the sources.

This Board will aid you in making such investigations by analyzing samples of water, and by furnishing to your engineer any information now in its possession bearing upon the question; and will, upon application, when you have further information to present, advise you further as to the most appropriate method of increasing your supply.

On Aug. 1, 1895, the water committee again applied to the Board for its advice, relative to taking an additional supply of water from the land in the Hoosac valley above Cheshire harbor and below the village of Cheshire. The Board replied to this application as follows:—

BOSTON, Oct. 3, 1895.

The State Board of Health received from you on Aug. 1, 1895, an application asking for the advice and approval of the Board of a plan for obtaining an additional water supply for the Adams fire district from the ground in the valley of the Hoosac River above Cheshire harbor and below the village of Cheshire by means of tubular wells, the water to be pumped into the main pipe leading from Bassett Brook reservoir, one of the present sources of supply to the town.

Accompanying the application is a report by your engineer, containing the results of investigations made by him of various sources in the vicinity of the town, and the Board has also caused a further examination of these sources to be made by one of its engineers. As a result of these investigations, it is found that the flow of the brooks at present used for the supply of the town and of two other brooks in the vicinity on September 6 and when there had been no rain for several days, was about as follows:—

|                          |                          |
|--------------------------|--------------------------|
| Bassett Brook, . . . . . | 275,000 gallons per day. |
| Dry Brook, . . . . .     | 90,000 gallons per day.  |
| Tophet Brook, . . . . .  | 127,000 gallons per day. |
| South Brook, . . . . .   | 315,000 gallons per day. |

Samples of water collected September 7 from your present sources of supply and from other sources examined have been analyzed, and a com-

parison between the results of these analyses and of the analyses of samples collected from these same sources in the earlier portion of the year may be made from the following table:—

| SOURCE.                                    | Hardness<br>September 7. | Hardness in<br>Earlier Portion of<br>the Year. |
|--------------------------------------------|--------------------------|------------------------------------------------|
| Tophet Brook, . . . . .                    | 7.6                      | 1.4                                            |
| Dry Brook, . . . . .                       | 9.4                      | 1.6                                            |
| Bassett Brook, . . . . .                   | 3.2                      | 1.1                                            |
| South Brook, . . . . .                     | 3.2                      | 1.6                                            |
| Test well above Cheshire Harbor, . . . . . | 11.0                     | <div> 10.3*<br/> 10.6*<br/> 14.8* </div>       |
| Renfrew well, . . . . .                    | 12.6                     | 12.3                                           |

\* Three test wells.

The results of the analyses show that the hardness of the water of Tophet and Dry brooks was several times as great in September as in the earlier portion of the year, while the increase in the hardness of the water of South Brook was comparatively small. From the results of the examinations it appears that a supply of water somewhat greater than the amount yielded by Bassett Brook and of equally good quality with respect to hardness, would be furnished by South Brook. The quality of this water is also satisfactory in other respects.

It appears from the report of your engineer that a storage reservoir having a capacity of about 43,000,000 gallons can be constructed upon this brook and that the water of this reservoir could be supplied to the town by gravity by laying a pipe to connect with the pipe leading from your present Bassett Brook reservoir. The estimates of cost indicate that the first cost of a supply from this source would be about two and one-half times as great as that from tubular wells in the valley of the Hoosac River above Cheshire Harbor; but the annual cost of maintenance, including interest, would not be proportionally greater, because the water of South Brook would be delivered to the town by gravity, and the cost of pumping would be avoided.

By taking a supply from South Brook the town would obtain a soft water of excellent quality for the purposes of a public water supply. The water of the test wells, on the other hand, though of excellent appearance and practically free from organic matter, is so hard, owing to the presence of lime in solution, that it would be undesirable for drinking and objectionable for many other purposes of a domestic water supply.

The Board regards it of importance to the health of the town to avoid very hard waters, and obtain as soft water as practicable. The water of South Brook is the most satisfactory in this respect, and the Board is of opinion that by the construction of a reservoir in the upper part of Dry Brook a softer water may be obtained in a dry time than is now obtained from this brook.

By the provisions of the act passed last spring, no authority is given to the town of Adams to take any source in Cheshire south of the southerly boundary of the former town of New Providence, which excludes South Brook. In view, however, of the excellent quality of water obtainable from this source, the Board would advise that you take measures to secure the right to take the water of this brook, subject to the right of the town of Cheshire to such an amount of water from this source as may be needed for the supply of the town in addition to the waters of Thunder and Kitchen Brooks when they shall have been fully developed.

The population of Cheshire has steadily decreased for the past fifteen years, and, moreover, the sources in the region from which its present supply is taken have not been fully developed, so that there is no present indication that any water need be drawn from South Brook for the supply of Cheshire.

The yield of South Brook, with a storage reservoir having a storage capacity of 43,000,000 gallons, would, in connection with your present sources, amount to about 1,100,000 gallons per day in the drier months of a very dry season.

Measurements made by your engineer in the early part of July indicate that at that time the consumption of water in the town amounted to 1,150,000 gallons per day, equivalent to 147 gallons per person per day. This is an excessive consumption and is greater than that of any other city or town in the State where records of the consumption of water are kept. There appears to be no good reason why the consumption should be larger than that of other towns where the conditions are similar, and by reducing to a reasonable amount the capacity of your present works, with the addition of a storage reservoir on South Brook, will be sufficient for the town till a large increase over the present population takes place.

**AMESBURY.** The Powow Hill Water Company applied to the State Board of Health March 18, 1895, for its advice relative to obtaining an additional supply of water from the ground near Main Street in that town. The Board replied as follows:—

Boston, June 6, 1895.

The Board has caused examinations of the present and proposed sources of supply and analyses of water from each of the sources to be made. From

parison between the results of these analyses and of the analyses of samples collected from these same sources in the earlier portion of the year may be made from the following table : —

| SOURCE.                                    | Hardness<br>September 7. | Hardness in<br>Earlier Portion of<br>the Year. |
|--------------------------------------------|--------------------------|------------------------------------------------|
| Tophet Brook, . . . . .                    | 7.6                      | 1.4                                            |
| Dry Brook, . . . . .                       | 9.4                      | 1.6                                            |
| Bassett Brook, . . . . .                   | 3.2                      | 1.1                                            |
| South Brook, . . . . .                     | 3.2                      | 1.6                                            |
| Test well above Cheshire Harbor, . . . . . | 11.0                     | <div> 10.3*<br/> 10.6*<br/> 14.8* </div>       |
| Renfrew well, . . . . .                    | 12.6                     | 12.3                                           |

\* Three test wells.

The results of the analyses show that the hardness of the water of Tophet and Dry brooks was several times as great in September as in the earlier portion of the year, while the increase in the hardness of the water of South Brook was comparatively small. From the results of the examinations it appears that a supply of water somewhat greater than the amount yielded by Bassett Brook and of equally good quality with respect to hardness, would be furnished by South Brook. The quality of this water is also satisfactory in other respects.

It appears from the report of your engineer that a storage reservoir having a capacity of about 43,000,000 gallons can be constructed upon this brook and that the water of this reservoir could be supplied to the town by gravity by laying a pipe to connect with the pipe leading from your present Bassett Brook reservoir. The estimates of cost indicate that the first cost of a supply from this source would be about two and one-half times as great as that from tubular wells in the valley of the Hoosac River above Cheshire Harbor ; but the annual cost of maintenance, including interest, would not be proportionally greater, because the water of South Brook would be delivered to the town by gravity, and the cost of pumping would be avoided.

By taking a supply from South Brook the town would obtain a soft water of excellent quality for the purposes of a public water supply. The water of the test wells, on the other hand, though of excellent appearance and practically free from organic matter, is so hard, owing to the presence of lime in solution, that it would be undesirable for drinking and objectionable for many other purposes of a domestic water supply.

The Board regards it of importance to the health of the town to avoid very hard waters, and obtain as soft water as practicable. The water South Brook is the most satisfactory in this respect, and the Board is of opinion that by the construction of a reservoir in the upper part of Dry Brook a softer water may be obtained in a dry time than is now obtained from this brook.

By the provisions of the act passed last spring, no authority is given to the town of Adams to take any source in Cheshire south of the southerly boundary of the former town of New Providence, which excludes South Brook. In view, however, of the excellent quality of water obtainable from this source, the Board would advise that you take measures to secure the right to take the water of this brook, subject to the right of the town of Cheshire to such an amount of water from this source as may be needed for the supply of the town in addition to the waters of Thunder and Kitchen Brooks when they shall have been fully developed.

The population of Cheshire has steadily decreased for the past fifteen years, and, moreover, the sources in the region from which its present supply is taken have not been fully developed, so that there is no present indication that any water need be drawn from South Brook for the supply of Cheshire.

The yield of South Brook, with a storage reservoir having a storage capacity of 43,000,000 gallons, would, in connection with your present works, amount to about 1,100,000 gallons per day in the drier months of a very dry season.

Measurements made by your engineer in the early part of July indicate that at that time the consumption of water in the town amounted to 1,150,000 gallons per day, equivalent to 147 gallons per person per day. This is an excessive consumption and is greater than that of any other city or town in the State where records of the consumption of water are kept. There appears to be no good reason why the consumption should be larger in that of other towns where the conditions are similar, and by reducing to a reasonable amount the capacity of your present works, with the addition of a storage reservoir on South Brook, will be sufficient for the town until a large increase over the present population takes place.

**AMESBURY.** The Powow Hill Water Company applied to the State Board of Health March 18, 1895, for its advice relative to obtaining an additional supply of water from the ground near Main Street in that town. The Board replied as follows:—

Boston, June 6, 1895.

The Board has caused examinations of the present and proposed sources of supply and analyses of water from each of the sources to be made. From

the information thus obtained the Board finds that the present sources are likely to be inadequate in a dry year for supplying the present consumers with water.

The analyses of samples of water taken from the test well at the proposed source show that the water is at present of excellent quality, and, although it may change somewhat in character with a continuous draught upon this source, it will probably remain of suitable quality for water-supply purposes, unless there should be a considerable increase in the population in the vicinity of the well.

The conditions, however, do not appear favorable for obtaining any large additional supply of water from this source, and, as it is the general experience of cities and towns that the amount of water consumed increases much faster than the population, both on account of the increasing proportion of the inhabitants supplied with water and the increasing use of water per consumer, it is not probable that the proposed additional supply would meet the requirements for more than a very few years.

The Board, therefore, believes it to be desirable, in order to provide adequately for the present and future needs of the town, and probably in the interest of true economy, to obtain a larger additional supply of pure water than can be obtained from the proposed source near Main Street, and advises that you make further investigations, with the aid of a competent engineer, to ascertain whether it is not feasible to obtain such a supply.

**BILLERICA.** J. Nelson Parker and other petitioners applied to the Board March 6, 1895, for its advice relative to the use of the water of Nutting's Pond in Billerica for fire and domestic purposes for that town. The Board replied to this application as follows:—

Boston, April 4, 1895.

The State Board of Health has considered your application relative to a proposed water supply to be taken from Nutting's Pond in Billerica, has had the pond examined by one of its engineers, and has caused a chemical and microscopical examination of a sample of water collected from it to be made.

The chemical examination shows that the water has a high color and contains a large amount of organic matter, much of which is in suspension; and the microscopical examination shows that a large part of the suspended organic matter is a minute organism, of a kind which is known to have caused bad tastes and odors in other water supplies of the State. The water, therefore, although not polluted by sewage, and no worse in other respects than that furnished to a few places in the State, cannot in its present condition be regarded as of satisfactory quality for the purposes of a public water supply.

The Board therefore advises the investigation of other available sources, to ascertain if a better one cannot be found; and it may also be well to determine whether the pond can be improved as a source of water supply by any changes which it is feasible to make in or near it, and to have samples of water collected from the pond at other seasons of the year and analyzed.

**BRADFORD.** An application was received from the Bradford Water Company for the advice of the Board, relative to the introduction of new water supply from Johnson's Pond in Boxford and Groveland, and as to the improvement of the existing supply by methods outlined by the engineer of the company. The Board replied to this application as follows:—

Boston, March 15, 1895.

Samples of water from your present source have been examined by this board from time to time since 1889; and, while the water at first was of very good quality, it has been deteriorating in recent years, and there is no reason to expect that it will become better, but rather that it will continue to deteriorate.

The quality of the water might be improved by proper treatment, but there is uncertainty as to whether it could be made a wholly satisfactory water, and the cost of thorough treatment might be large in comparison with the cost of obtaining a satisfactory water in other ways; moreover, the capacity of the source is but little in excess of the amount of water now impounded. The Board, therefore, believes that the present source should be abandoned as soon as a better one can be made available.

The Board has caused examinations to be made by its engineers of all the sources from which it seemed at all probable that a satisfactory supply for the town of Bradford might be obtained; and from this examination concludes that there is no opportunity to obtain a satisfactory groundwater supply, and that Johnson's Pond is the most appropriate source from which to take a supply of surface water.

An analysis of water from this pond, taken in connection with an examination of the pond and its drainage area, shows that the water is of good quality, and suitable for all the purposes of a public water supply; and the pond will furnish a sufficient quantity of water to supply the towns of Bradford, Groveland and Boxford, and still leave as much water as is necessary to meet the requirements of the mills situated upon the stream which flows from the pond, for all purposes except water power.

The plan for improving the quality of the water from the present source, involving the construction of new works, as outlined in the report of your engineer, contemplates passing all of the water used through the existing distributing reservoirs, so that a portion of the iron contained in the water may become oxidized, and settle to the bottom of the reservoirs.

The plan proposed by him should cause a considerable improvement in the quality of the water, which might be increased somewhat if the water were pumped to a greater height than the water in the reservoir, and made to come in contact with the air as much as possible in falling. A still greater improvement would result if, in addition to letting the water drop through the air, it were given further opportunity for aeration by passing it through a filter composed of fragments of coke large enough to permit water and air to pass very freely. This filter should be situated above the level of the water in the reservoirs, and should have a surface area of about 400 square feet.

**BROOKFIELD.** The water commissioners of Brookfield applied to the Board Feb. 6, 1895, for its advice relative to taking a public water supply from South Pond in that town. Advice was also asked as to the "use of this source in common by the towns of West Brookfield and Warren," in addition to Brookfield, through the medium of the same works. The Board replied to this application as follows : —

Boston, July 11, 1895.

The Board finds that the quality of the water at the northerly end of the pond is at times unfavorably affected by the back flow of water from Quaboag Pond, the water of which is, in its natural state, inferior to that of South Pond, and is also polluted by the sewage discharged into its feeders from the town of Spencer; but analyses of samples of water collected at a distance from the outlet of the pond show that if the back flow from Quaboag Pond is prevented, South Pond will furnish a water of excellent quality for all the purposes of a public water supply.

The quantity of water which the pond will furnish is undoubtedly much in excess of the quantity which will be required for the supply of the town.

In addition to the examinations of South Pond, the Board has caused a general examination to be made of other sources from which it seemed possible that a supply might be obtained, and has also caused analyses to be made of samples of water collected from these sources. These examinations were not carried far enough to be wholly conclusive, but they did not indicate that there was any more appropriate source than South Pond from which to obtain a supply for the town.

You also stated in your application that "advice is desired as to the suitability and sufficiency of this source for the towns of West Brookfield and Warren if supplied in common with Brookfield through the medium of the works as proposed by the latter town." It has already been indicated that if provision is made for preventing the back flow from Quaboag Pond the water of South Pond will be of suitable quality for water-supply purposes; and the quantity of water which this source will furnish is sufficiently large to supply all three towns for a long time in the future.

In the absence of any request for advice from the towns of West Brookfield and Warren, the Board has made no investigations for the purpose of ascertaining whether the three towns named can best obtain a supply of water by taking it from this source through the medium of a single system of works.

**COHASSET.** The Cohasset Water Company applied to the Board Nov. 22, 1894, for its advice relative to increasing their water supply by means of driven wells, or one large well, about 1,000 feet south of the present system of driven wells. The Board replied to his application as follows:—

Boston, July 11, 1895.

The Board has caused analyses to be made of samples of water sent in by you from one of the test wells at this place, and finds that the water is one which has at some time been polluted and subsequently very thoroughly purified by its passage through the ground. It seems probable that if water were pumped continually from a well or wells at this place, a part of the water would come from the populated territory north-east of the railroad, and that, in addition to showing to a still greater degree the effect of previous pollution, it might also be less perfectly purified by its passage through the ground. For these reasons the Board does not regard this source as a desirable one from which to take an additional water supply.

In view of the undesirable character of the water of the proposed source, the Board has caused a general examination to be made of other surface and ground-water sources in the vicinity of the town. It finds that the water of the surface sources has generally a high color and contains in most cases a large amount of organic matter, mainly of vegetable origin; and, while it is possible that at least one of these might be made to furnish sufficient quantity of water, the quality of the water would not be nearly so satisfactory as that of a good ground water.

The examinations indicate that the most favorable locality in which to make investigations for a ground-water supply is in the vicinity of Bound Brook, above the village of North Scituate. The conditions here are not on the whole very favorable for obtaining a supply of this kind, but so far as could be judged from surface indications there is no more favorable locality within a reasonable distance of the town, and in view of the comparatively small amount of water needed, it seems possible that a satisfactory supply of ground water may be obtained at this place.

The Board will, upon application, advise you further in this matter when additional investigations have been made, and will furnish you with such information as may be in its possession concerning the various sources of water supply in the vicinity of the town.

DIGHTON and SOMERSET. An application was received Jan. 17, 1895, from James H. Flint and others (petitioners for incorporation as the Dighton and Somerset Water Company), for the advice of the Board relative to the taking of the waters of Muddy Brook and Segreganset River and their tributaries in the town of Dighton, and the water from any artesian or other wells which may be dug, bored or driven for the purpose in these towns, as sources of domestic water supply for Dighton and Somerset. The Board replied to this application as follows : —

Boston, March 25, 1895.

The Board has caused examinations of the proposed sources of supply to be made, as far as has been found practicable at this season of the year. Samples of water from Muddy Brook, Sunken Brook and the Segreganset River have been analyzed, and each has the brownish color and other characteristics which water acquires from contact with vegetable matter in swamps or shallow ponds, and on this account the water taken directly from either of these streams would not be of entirely satisfactory quality.

The water-sheds of both Muddy Brook and Sunken Brook are so small that they will not furnish enough water to supply the towns in a dry summer, unless a considerable amount of the water flowing in the wetter portions of the year is stored in reservoirs. There does not appear to be an opportunity for building reservoirs upon these streams of sufficient depth to prevent the water from deteriorating unless the reservoirs are deepened by excavating; and in order to obtain a sufficient amount of storage in this way the reservoirs would be very costly.

The Segreganset River has a much larger water-shed than the brooks above referred to, and can readily be made to furnish all of the water required for both towns.

A general examination was made of other sources, and there seemed to be more favorable opportunities for obtaining a water supply in Dighton than in Somerset; and, should it be found upon further investigation that, as now seems probable, the supply for both towns should come from sources in the town of Dighton, the two towns could be supplied more economically from one system of works than from independent systems.

Owing to the somewhat swampy character of the water flowing in most of the streams in this vicinity, it is desirable that a supply of good ground water should be obtained if possible; and the Board advises that investigations be made to determine whether it is feasible to obtain a supply of this kind, but cannot with its present information advise definitely as to the best place for making the investigations.

The Board will, if you so request, give you further advice later in the year, if you have more definite information to present as to the feasibility

obtaining a ground-water supply, or should find a more satisfactory surface-water source.

On April 26 the Board received a further application from the petitioners for further advice relative to the use of the water of the Swamp Brook and of the Segreganset River, or of so much of either source as may be necessary to supplement a ground-water supply. The Board replied to this second application as follows:—

BOSTON, May 25, 1895.

The State Board of Health received from you April 26, 1895, an application for further advice relative to using, for the water supply of the towns of Dighton and Somerset, the water of Pine Swamp Brook and of Segreganset River, or so much of the water of either source as may be necessary to supplement the supply obtained from the ground. You also state that additional information has been obtained as to the character of ground in the vicinity of these streams.

The Board in its last reply made the following statement: "Owing to the somewhat swampy character of the water flowing in most of the streams in this vicinity, it is desirable that a supply of good ground water should be obtained if possible, and the Board advises that investigations be made to determine whether it is feasible to obtain a supply of this kind," and concluded its reply as follows: "The Board will, if you so request, give further advice later in the year, if you have more definite information presented as to the feasibility of obtaining a ground-water supply, or should find a more satisfactory surface-water source."

Further examinations and analyses made by the Board indicate that the waters of Pine Swamp Brook and the Segreganset River, owing to their brownish color and accompanying taste and odor, would not be of satisfactory quality for water-supply purposes unless taken indirectly by filtration through the ground.

The additional information submitted by you as to the character of the ground in the vicinity of these streams was obtained by driving three test wells near the junction of Pine Swamp Brook and the Segreganset River. These tests show that there is more or less porous material beneath the surface from which water can be pumped, and, although the conditions do not appear to be favorable for obtaining any very abundant supply of ground water, yet it may be feasible to obtain the comparatively small quantity needed for these towns by means of a well supplemented by collecting cisterns or galleries extended for a sufficient distance up the valleys of the Swamp Brook and the Segreganset River.

Two samples of water were procured from the wells during the tests; but,

judging from the analyses of samples of water collected from a spring and from two wells not very far away, it is probable that the water to be obtained from the ground would be of good quality.

The examinations have been sufficiently extended to indicate that the ground in the vicinity of the Pine Swamp Brook and the Segreganset River is likely to be the best source within the limits of these towns from which to take a water supply; but the information at present available is too limited to enable the Board to give a definite opinion upon this point.

**EDGARTOWN.** An application was received from Joseph K. Nye, March 12, 1895, petitioner for incorporation as the Edgartown Water Company, for the advice of the Board relative to taking the water of certain springs in a valley south-west of the village of Edgartown as a source of public water supply. The Board replied to this application as follows:—

Boston, March 26, 1895.

The State Board of Health received from you on March 12, 1895, an application relative to a proposed water supply for Edgartown, Mass., which contains the following statement: "The proposed source of supply is from a tract of land situated about four thousand feet in a south-westerly direction from the village of Edgartown. The land is situated in a valley running in a south-easterly direction, the point of location being at the head of this valley, something over a mile from Edgartown Harbor. At this point are a number of springs, and it is proposed to drive a sufficient number of pipe wells to yield the required amount of water."

The Board has caused an examination of the locality referred to to be made by one of its engineers; but, as the ground has not been tested by driving wells or otherwise, it is impracticable at the present time to give any definite opinion as to the quantity and quality of water to be obtained from the proposed source. Judging from surface indications, however, it is not improbable that a sufficient quantity of water may be obtained from the ground in this vicinity; and, judging from experience with the water supplies of Cottage City and Vineyard Haven, which are derived from ground apparently similar in character, it is probable that the water will be of good quality.

The Board will advise you further upon this subject when you have made tests of the ground and have additional information to present.

**GLOUCESTER.** The Board received the following application July 3, 1894, from the mayor of Gloucester, for the advice of the Board relative to the water supply of that city:—

GLOUCESTER, Mass., June 30, 1894.

*To the State Board of Health.*

The city of Gloucester, by its duly appointed committee, desires and respectfully requests that further and more complete investigations of its present and prospective sources of water supply be made during this year, in order that safe and final conclusions may be reached by the city concerning the present and ultimate capacities of the sources from which water is now being actually supplied to the city, and those which may be added in reinforcement when an increase becomes necessary, among the latter to be included Chebacco Pond, with its tributaries and water-sheds. The city desires that the question of quality, in each case, be exhaustively considered; that present and future improvements which may be necessary to raise the quality to the highest degree attainable with reasonable economy be indicated; and that, so far as possible, some idea of the relative costs of making these improvements in each case be given.

Directions have been given to the city engineer "to obtain all records of varying depths of water in the present sources and kindred data which may have any bearing upon the case," and the city engineer will follow any suggestions which the Board may give in this line, and will promptly make such returns as the Board may indicate.

The city desires and respectfully requests that analyses of the waters of the sources involved be made with regularity during the remainder of this year, the samples to be taken simultaneously, if practicable.

For the joint special committee on water supply of the city of Gloucester,

(Signed)

BENJ. F. COOK,

*Mayor, and Chairman of Committee.*

To this application the Board replied as follows:—

BOSTON, April 12, 1895.

In accordance with your request, an engineer of the Board visited your present and prospective sources twice in the month of July, 1894, and made arrangements for having samples of water taken from the present sources by your city engineer, acting in conjunction with a representative of the Gloucester Water Company, and from prospective sources by your city engineer. These samples were collected about once a month until February, 1895, making the total number of samples collected and analyzed 64.

From time to time your city engineer and Mr. Percy M. Blake, the engineer especially engaged upon the water-supply investigation, have furnished information and plans, giving the results of surveys and observations bearing upon the question of the capacity of present and proposed sources;

and, finally, we have received the supplementary report of Mr. Blake upon a municipal water supply for the city of Gloucester, dated March 9, 1895.

With the information thus furnished and that obtained by several examinations made by an engineer of this Board, the questions submitted by you have been carefully considered.

The conclusions reached by the Board as a result of this consideration are substantially the same as those contained in the reply to you upon the same subject, dated April 27, 1894, which were as follows:—

“The Board finds that the present sources have sufficient capacity in a dry year to supply the quantity of water now used by the city; but the population now supplied is much less than the total population, and the amount of water consumed is increasing from year to year, so that it will be necessary before long either to develop the sources now used or to obtain a further supply from other sources. If the present sources and those in their vicinity should be fully developed they would furnish fully double the quantity of water now used, and make a further supply unnecessary at the present time.

“The water supplied from the present reservoirs of the Gloucester Water Company is practically free from pollution by sewage, and in other respects it is a fairly satisfactory water for the purposes of a public water supply, and is somewhat better at the present time than the water in Chebacco Lake. It could undoubtedly be improved, however, by the removal of stumps, soil and vegetable matter from the bottom and sides of the reservoirs. The water from other sources near the present ones in West Gloucester has not been analyzed, but from an examination of these sources it seems probable that they will furnish as good water as the sources now supplying the city.

“Chebacco Lake will furnish a somewhat larger quantity of water than could be obtained from all of the available sources in West Gloucester if they were fully developed, and is probably the most available source of water supply for Gloucester, independent of the present works. As already indicated, the water is not quite as good as that now supplied to the city, and it is doubtful if it would prove a satisfactory water for water-supply purposes unless improved in some way, which cannot be determined with the information now available.

“The Chebacco ponds are located in the towns of Essex, Hamilton and Wenham, and are only a short distance from Manchester, and may prove the most available source of water supply or additional water supply for these towns; moreover, it is not improbable that they may prove the most available source from which to take an additional water supply for Salem and Beverly, when the capacity of the sources from which these places are now authorized to take water has been reached. Under these circumstances, the Board is of the opinion that the Chebacco ponds are not at

present the most appropriate source of supply for the city of Gloucester; and if rights in these ponds are granted to Gloucester, they should be limited by proper reservations for other places."

Now that further information is available and further examinations have been made, the Board is enabled to give more specific advice in some respects and to answer more fully the questions asked by you.

The Board now believes that the present sources and others in their vicinity can, at a reasonable cost, be improved and developed to such an extent that they will furnish about three times the quantity of water now used, and the quality of the water to be obtained from the added sources will be as good or better than that now supplied to the city from the present sources.

The nature of the work to be done to improve the quality of the water of the sources now used is, as indicated in the former reply, the removal of stumps, soil and vegetable matter from the bottom and sides of the reservoirs. In adding new sources the same policy should be pursued with regard to any reservoirs which may be built, and suitable channels should also be provided for collecting and conveying the water to the reservoirs in such a manner that it will not be injuriously affected by coming in contact with leaves, peat and other vegetable matter in swamps.

Chebacco Pond will furnish a somewhat larger quantity of water than all of the available sources in West Gloucester, when developed as above indicated; but the quality of its water is not quite as good as that supplied from the sources now used, and would compare still more unfavorably with the quality of the water to be obtained from the West Gloucester sources when improved and developed. The investigations thus far made have not shown that the quality of the lake water can be improved at what would be, at the present time, a reasonable cost.

The cost of taking water from Chebacco Lake would be considerably larger than that of properly developing all of the available sources in West Gloucester, with the further disadvantage in the former case that practically the whole expenditure has to be made at one time, while in the latter the expenditures for different additions and developments can be made from time to time, as an increased amount of water is needed.

If the city of Gloucester, by reason of its growth and the increased use of water, should reach the capacity of the sources in West Gloucester, Chebacco Lake will probably be at such time the most appropriate source from which to take an additional water supply.

**GREENFIELD.** An application was received from the selectmen of Greenfield, Nov. 30, 1894, for the advice of the Board relative to taking an additional supply of water for the town from the Green

River at a point near the "Poor Farm." The Board replied to this application as follows : —

Boston, March 15, 1895.

You state that it is the purpose to take water at a point on the west boundary of land owned by the town of Greenfield and known as the "Poor Farm;" and the Board has since been informed that the water is to be taken from a crib or well sunk in the gravel beside the river, rather than directly from the river itself. It is further understood that this supply is to be obtained by pumping, and is to supplement the present gravity supply from Glen Brook during the drier portion of the year.

The water of the Green River is somewhat harder than that obtained from the present source, but is not hard enough to be objectionable. In other respects the analyses indicate, as far as analyses can, that the water is of excellent quality for all the purposes of a public water supply. There is a risk, however, in taking water directly from a stream which has any population near it. But, in the present case, the risk is comparatively slight on account of the extremely small population. Still it would be advisable to take the water from a well sunk near the river, as proposed, in preference to taking it directly from the river.

Before sinking a well of this kind, examinations should be made to determine that the material adjacent to the river is porous to a considerable depth below the level of the water in the river; and, if such material should not be found at the point indicated in your application, the Board advises that you should make similar examinations of the ground beside the river near the point where Allen Brook enters it, as the examinations made by one of the engineers of the Board indicate that favorable ground in which to sink a well may be found at this place.

GROTON. The committee on water supply of Groton applied to the Board Jan. 12, 1895, for its advice relative to Baddacook Pond and springs near Cady Pond as sources of water supply for Groton. The Board replied to this application as follows : —

Boston, Nov. 4, 1895.

The Board has caused an examination of these sources to be made by one of its engineers, and samples of the water to be analyzed.

The quality of the water of springs near Cady Pond is excellent in most respects, but its hardness, which appears to be due to the presence of limestone in the ground through which the water percolates, is such as to make it very unsatisfactory for many of the purposes of a public water supply. There is much doubt also as to whether the quantity of water which the springs would furnish in a very dry season would be sufficient for the supply of the town after water shall have come into general use.

Baddacook Pond would furnish an abundant supply of water for the town, and chemical analyses show that its hardness would be only about one-third of that of the springs near Cady Pond. The water is somewhat colored, however, and contains a considerable amount of organic matter. Microscopical examinations, moreover, indicate that it may contain at times in summer a considerable number of minute organisms, which impart water an unpleasant taste or odor.

With regard to the comparative merits of the two sources, it may be said that Baddacook Pond would be preferable as a source of public water supply, all things considered, to the springs near Cady Pond, but there is no doubt that if a source capable of furnishing a sufficient supply of ground water of good quality could be obtained, it would be more satisfactory than the water of Baddacook Pond. With a view to learning whether it was feasible for the town to obtain a ground-water supply within a reasonable distance, the Board has caused an examination to be made in a general way of the territory in the vicinity of the town. As a result of this investigation, the Board finds that the surface indications appear to be favorable to obtaining a considerable quantity of water from the ground at several places, the most favorable being in the vicinity of Baddacook Pond, particularly along the south-westerly side of the pond and in the valley of a small tributary which enters the pond on its westerly side. Chemical examinations of the water of springs in the latter locality indicate that the hardness of the water is about the same as that of the water of Baddacook Pond.

The Board would, therefore, advise that, before deciding definitely upon a source of supply, further investigations be made, with a view to determining whether it is feasible to obtain from the ground at either of these places a water of satisfactory quality and in sufficient quantity for the supply of the town. The Board will, upon application, advise you further in this matter when you have additional information to present.

**HATFIELD.** The selectmen of Hatfield applied to the Board Jan. 1, 1895, for its advice relative to taking the water of a brook in the westerly part of the town as a source of public water supply for Hatfield. The Board replied as follows:—

Boston, March 1, 1895.

At the time when an engineer of the Board visited Hatfield to examine the proposed source, there was so much snow upon the ground that it was not feasible to reach the site which your engineers regarded as most satisfactory for the proposed dam, but he succeeded in obtaining a sample of water from the brook between the upper and lower sites for the dam.

The analysis of this sample, taken in connection with the character of the water-shed, indicates that the water is of excellent quality for the purposes of a public water supply.

It was not feasible under the circumstances to judge from an examination of the locality whether the brook at the upper site will furnish a sufficient quantity of water for the town; but the report of your engineers of the measured flow in September, 1894, indicates that it will do so.

The Board regards the source as an appropriate one from which to take a water supply for the town of Hatfield.

**HAVERHILL.** The water board of Haverhill applied to the State Board of Health Jan. 15, 1895, for its advice relative to introducing an additional supply of water for Haverhill from East Meadow River in that city by constructing a dam and making a storage basin, the water to be pumped from this basin to Lake Kenoza, the source of the present high-service supply of the city. The Board replied to this application as follows:—

Boston, June 6, 1895.

Regarding this source of supply and the method of utilizing the water from it you make the following statement:—

“This additional supply for the city of Haverhill is proposed to be taken from the East Meadow River, in the easterly portion of the city, at Millvale, where it is proposed to construct a dam and create a storage basin. The area of the basin will be approximately 47 acres; the depth of water at the dam will be about 14 feet in the deepest place. The estimated capacity of this basin is 118,000,000 gallons. It is proposed to remove all mud and vegetable matter from the site of the basin. The area of the water-shed above the dam is approximately 7.75 square miles.

“A pumping station will be erected, with a pumping plant of sufficient capacity to pump all of the water needed in any year, during the five or six months of greatest flow. The water to be pumped through about one mile of twenty-four-inch pipe to Kenoza Lake, the source of the present high service supply of Haverhill.

“This lake has an area of 225 acres at elevation 110. The estimated storage capacity is 600,000,000 gallons in the upper ten feet in depth, or to the top of the intake of the new pumping station proposed to be built at Kenoza Lake in connection with this improvement.

“The difference in level of the Millvale basin and Kenoza Lake is 64 feet, the proposed high-water level of the former being at elevation 46.

“The plan of operation will be to pump the flow of East Meadow River into Kenoza Lake and store it there, using the storage in the Millvale basin if necessary.

basin will equalize the flow of the stream and allow of a pump of no greater capacity than the average daily flow for the as much of it as is required by the consumption."

application was accompanied by the report and plans of your Mr. Freeman C. Coffin, relative to providing an additional water for your city.

tate Board of Health has, from time to time, for many years, samples of water from the present sources of supply, viz., Kenozaystal Lake, Round Pond and Plug Pond, and regards the water these sources except Plug Pond as of suitable quality at the time for drinking.

amount of water consumed by the city is not definitely known, only the portion pumped from Kenoza Lake is measured, but, from the estimates made by your engineer and similar estimates of an engineer of this Board, the average consumption of water in three years from 1892 to 1894, inclusive, was 2,800,000 gallons which is in excess of the capacity of the present sources of supply, of Plug Pond, in a series of dry years. It therefore follows additional supply should be provided at once, or that measures be taken promptly to diminish the consumption of water.

amount of water consumed in Haverhill is very large in proportion to population, as will be seen by the following comparison with the consumption in other cities in the State where the manufacture of boots and shoes is the chief industry:—

| NAME OF CITY.                | Estimated Population in 1893. | AVERAGE DAILY CONSUMPTION OF WATER IN GALLONS, 1892-94, INCLUSIVE. |                 |
|------------------------------|-------------------------------|--------------------------------------------------------------------|-----------------|
|                              |                               | Total.                                                             | Per Inhabitant. |
| including Saugus), . . . . . | 68,378                        | 3,770,000                                                          | 55              |
| 1, . . . . .                 | 30,600                        | 2,800,000                                                          | 92              |
| . . . . .                    | 31,200                        | 767,000                                                            | 25              |
| ough,. . . . .               | 15,524                        | 441,000                                                            | 28              |

is no doubt that the consumption of water in Haverhill is unusual, and that it would be feasible to diminish it by preventing the loss and waste of water to such an extent that the present sources would supply considerably more than the present population.

Analyses of samples of water collected from the East Meadow River at the mouth of the proposed storage reservoir, together with an examination of the drainage area of this river, show that the water is practically free from pollution by sewage, but that it contains organic matter, and has a brown color derived mainly from the swamps upon the water-shed; so that, if

conveyed directly to the city, it would be less attractive in appearance and probably less palatable than the water from the present sources.

This objection would be overcome to a large extent by pumping the water into Kenoza Lake. The mingled waters will be of much better quality than the water of the East Meadow River, and will bleach and otherwise improve in quality by storage in the lake. When it becomes necessary to take a large proportion of the water from the East Meadow River, it may prove desirable to improve the quality of the water of the river by thoroughly draining the swamps upon the water-shed, so that the water will not take up so large an amount of organic and coloring matter. If the population upon the water-shed of the river should increase materially, it may be necessary to take efficient measures to prevent the waste matters from entering the river.

Owing to the large size of the water-shed of the East Meadow River above the proposed dam, there is no doubt that the quantity of water which flows in the river during the year is much larger than the quantity flowing into all of the present sources; and, since the ponds and lakes now in use have a very large storage capacity, a large additional supply could be obtained by pumping the portion of the flow of the river which could be made available without constructing a storage reservoir upon it. A still larger supply, however, can be obtained by constructing the proposed storage reservoir upon the river, and if all of the mud and vegetable matter is removed from its site, as proposed by you, the quality of the water should improve rather than deteriorate by storage in this reservoir.

As the result of all of its examinations, the Board believes that the proposed source can be made to furnish a water of satisfactory quality, and that it is the most appropriate source from which to take an additional water supply for the city of Haverhill.

**HOLDEN.** The committee on water supply for the town of Holden applied to the Board Jan. 23, 1895, for its advice relative to taking the water of Pine Hill Reservoir in that town as a source of domestic water supply. The Board replied to this application as follows:—

Boston, March 19, 1895.

The proposed source would furnish an abundant supply of water, but the quality is likely to be somewhat unsatisfactory unless the town obtains control of and improves the reservoir, which was not originally prepared with a view to storing water for domestic use, and is now drawn very low in dry seasons for use at the mills below, and improves the quality of the water entering the reservoir by preventing the discharge of manufacturing wastes into it, and by draining swamps above the reservoir.

In addition to the objection that this water is not likely to be wholly satisfactory in quality, there is the further objection that the reservoir is not high enough to furnish by gravity an efficient fire service in the town.

In view of these unfavorable features of the source proposed by you, the Board has caused a further examination of Muschopauge Pond in the town of Rutland to be made, in order to ascertain whether this source, which has recently been considered in connection with a proposed water supply for Rutland, is not also an appropriate source of supply for Holden. This pond will furnish a water of better quality than Pine Hill Reservoir, is high enough to provide by gravity an ample pressure for fire purposes in all parts of Holden, and the quantity of water is sufficient for both towns.

Measurements from the State map indicate that the additional length of a pipe required to take water from the pond instead of from Pine Hill Reservoir will be about 0.7 of a mile; but the advantages of taking a water supply from this source are so great that the Board regards it a more appropriate source for the town of Holden than the one proposed; subject, however, to the right of the town of Rutland to take as much water as it needs from the pond.

**HOLYOKE.** An application was received from the water board of Holyoke Nov. 29, 1895, for the advice of the State Board of Health, relative to a proposed additional water supply, to be taken from the south-west branch of the Manhan River at a point about one and one-half miles above Russellville.

The Board replied to this application as follows:—

Boston, Jan. 3, 1896.

The State Board of Health received from you on Nov. 22, 1895, an application with reference to a proposed additional water supply for the town of Holyoke, to be taken from the south-west branch of the Manhan River, at a point just below the confluence of the Manhan and Tucker rivers, about two and one-half miles above the village of Russellville in the town of Southampton. You propose at first to divert the natural flow of the brook through a twenty-inch or twenty-four-inch pipe into Ashley Pond, and of your present sources of supply, by gravity, and subsequently, when an increase in the use of water by the city makes necessary a larger supply than the natural flow of the brook will furnish in connection with present sources, you propose to construct storage reservoirs at favorable sites along the stream and its tributaries.

Our investigations with reference to storage reservoirs upon the watershed of the proposed source indicate that a reservoir of a capacity of about

760,000,000 can be constructed on the Manhan Brook, about one and one-half miles above its junction with Tucker Brook, and that another reservoir of large capacity can be constructed at the junction of Manhan and Tucker brooks.

The Board has caused an examination of the proposed source of supply to be made and samples of the water sent in by you to be analyzed. These analyses indicate that the water of the proposed source is soft, and otherwise of good quality for domestic use.

This water-shed, when developed by the construction of storage reservoirs at the sites indicated, will, in connection with your present sources, furnish a sufficient supply for the city for a very long time in the future at the present rate of increase in population, if the consumption of water does not exceed about 90 gallons per inhabitant.

The taking of the proposed source by Holyoke does not appear to conflict with the interests of other growing communities in the vicinity, so far as the future water supply of these places is concerned, and the source is an appropriate one for additional water supply for Holyoke.

The question as to the size of pipe to be used for conveying water from the south-west branch of the Manhan River to Ashley Lake is largely one of cost, and depends to a considerable extent upon the future growth of the city. If the city should continue to grow for many years in the future at about the same rate that its past growth seems to indicate, there will probably be little difference in the ultimate cost whether a twenty-inch or twenty-four-inch pipe is used. If the increase in population and in the use of water should be less rapid in the future than in the past, a twenty-inch pipe would probably be somewhat more economical. There is an advantage in the use of the larger pipe, however, in that, even before its full capacity is required to prevent a shortage of water, it would be of great advantage in filling the present ponds and reservoirs in the spring, keeping them at a higher level in the summer, and maintaining a better quality of water.

**KINGSTON.** In the report of the Board for 1888 the following statement appears in regard to the water supply of Kingston : —

In the town of Kingston there are at present two water supplies, one of which, supplying water for about forty or fifty families, has for many years conveyed its supply to the houses for a considerable part of the distance in a lead pipe one and one-half inches in diameter. As there was some apprehension in the town lest injury might occur to the persons using this water, it was thought best to refer the matter to the State Board of Health. It was stated that in certain instances persons who used the water had been made ill. So far as could be learned, however, the

ptoms which had been referred to this cause were not indicative of lead-poisoning.

Samples of the water were obtained from the pipes at Kingston, and submitted to chemical analysis. The result of the analysis indicated that the water was dissolving quantities of lead, so minute that they could not be regarded as injurious to health; but the fact that any lead was dissolved by this water may imply that under certain circumstances the quantity of lead contained may be large enough to become injurious, and we are glad to learn that since the date of this inquiry the works of the Water-duct Company have been bought by the town of Kingston, and the use of the lead pipe discontinued.

The public water supply of the town, after the general introduction of water and the discontinuance of the works of the old company, was obtained from a well near the mill-pond upon the Thames River. This was subsequently increased by means of a water-gallery about three hundred feet in length, extending along the bank of the pond and river above the well. In 1891 the filter-ery was still further extended to a length of about twelve hundred feet.

In August, 1895, information was received by the Board from several sources that persons using the water of the Kingston water-works exhibited well-marked symptoms of lead-poisoning. About the same time a verbal request was made by the Kingston water-works that an analysis of the water supplied by the town should be made. The Board then caused an investigation to be made, which proved conclusively that at least twenty-five of the consumers of the water of the public supply at Kingston presented undoubted symptoms of lead-poisoning.

The following conditions were also found to exist:—

1. An unusually free use of lead pipe through the town. The service-pipes were all of lead, and the average distance of the houses from the street is greater than that which prevails in most villages, so that longer pipes are necessary for supplying the houses. There are several instances in which houses are situated at an unusual distance from the street main, so that several hundred feet of lead pipe are used to connect the house with the main, and in these cases the most severe cases of lead-poisoning have occurred. In one instance, where there were long stretches of lead pipe, the water did not suffer, and in these cases it was found that care was

taken not to use the water which had remained in the pipes over night, but to let it run off before using. Samples of water were obtained from the taps at several houses, the water having been allowed to stand over night in the pipes, and in nearly every instance the amount of lead found to exist in such samples was found to be considerably beyond the limits usually regarded as dangerous to health. These amounts were found to be as high, in several instances, as  $\frac{1}{4}$ ,  $\frac{1}{3}$  and  $\frac{1}{2}$  grains per gallon.

In consequence of the results of these investigations, the Board sent the following communication to the board of water commissioners of Kingston : —

Boston, Sept. 23, 1895.

The State Board of Health has considered your request for advice in regard to the healthfulness of the present water supply of the town, and, though not having completed its investigations, it has found that the use of lead pipes in the distribution of this water has seriously injured the health of many citizens of the town, and endangers the health of all who use the water so conveyed.

The Board, therefore, recommends the immediate removal of all lead pipes in the town, wherever they are used for conveying water for domestic use, either as service pipes or as street mains.

The general subject of lead-poisoning will receive fuller attention in a later report of the Board.

LEICESTER. An application was received from the water commissioners of Leicester, Jan. 29, 1895, for the advice of the Board relative to taking the water of Asnebumskit Pond in the town of Paxton as an additional source of water supply for Leicester. The Board replied to this application as follows : —

Boston, Feb. 5, 1895.

The State Board of Health received from you on Jan. 29, 1895, an application relative to taking an additional water supply for the Leicester water supply district from Asnebumskit Pond in the town of Paxton, and on the same day received an application from the selectmen of the town of Paxton relative to taking a water supply for that town from the same source.

The examinations made by the Board lead it to conclude that the water of this pond is of suitable quality for all the purposes of a public water supply, although it would be advisable to take first the water of certain

at the southerly end of the pond to the extent of their capacity on of the better quality of the water, and to supplement the supply of the springs with water taken from the pond. The pond will furnish an ample quantity of water to meet the requirements of both communities from its situation with relation to the sources which at present supply Leicester with water by gravity and to the town of Paxton, the Board regards it as an appropriate source of water supply for both places.

LEICESTER. An application was received June 6, 1895, from the water committee of Leominster, for the advice of the Board as to an additional water supply to be obtained by constructing reservoirs upon Fall Brook in that town. The Board replied to the application as follows:—

Boston, Aug. 12, 1895.

The State Board of Health received from you on June 6, 1895, an application relative to a proposed increase in the system of water supply of the town of Leominster, and subsequently (July 10) received from your committee blue-print copies of your proposed plans, showing locations for proposed storage reservoirs on Fall Brook in the south-westerly part of the

town. The Board has caused an examination of the proposed source of supply to be made by one of its engineers, and has also caused the water of Fall Brook to be analyzed. The analyses show that the water has but little iron, is soft, and is in other respects a surface water of good quality.

In constructing the lower reservoir on Fall Brook, as indicated on the plan submitted, the capacity of all works supplying the town will be increased to 2,000,000 gallons per day in a very dry season, and possibly to 3,000,000 gallons per day at more, depending upon the amount of water lost by leakage. If the upper reservoirs indicated on the plan should be constructed, the capacity of the works would not be further increased by more than about 1,000,000 gallons per day, an amount which would meet the increasing demand of the town for only a short time after the consumption of water had reached the capacity of the original works and proposed lower reservoir. Estimates of cost have been submitted, but it seems probable that a detailed statement will show that the cost of constructing these reservoirs, or either of them, will be found too great in proportion to the increase in supply to be justified thereby to warrant the expense.

The proposed lower reservoir, according to the plan, will cover an area of 15 acres, a portion of which, amounting to 14.8 acres, consists of pasture and meadow land, the soil of which is mud or peat, extending in some places to a depth of more than 8 feet. Samples of soil collected from several test pits at different depths from 6 inches to 3 feet beneath the

surface in the swamp and meadow area indicate that the material of this area is composed very largely of organic matter.

It is understood that it is proposed to prepare the reservoir thoroughly for the storage of water by removing all the soil and vegetable matter from the area to be flowed, excepting from the swampy portions, and that these portions are to be covered with sand or gravel, or other suitable material from the sides of the reservoir.

The experience in this State where reservoirs have been thoroughly prepared for the storage of water by the removal of all of the soil and vegetable matter from the bottom and sides has been an extremely satisfactory one, and this method should be followed in the construction of the proposed reservoir wherever the depth of soil and vegetable matter is not so great as to render it very expensive. In the swampy portions of the reservoir, where the depth of peaty and vegetable matter is so great as to render it impracticable to remove it all on account of the great cost of the work, that portion of the peat around the edges of the mass where it is less than two feet deep should be removed, and all of the trees, bushes and stumps from the other portions, and the remaining swampy material covered with sand, gravel or other suitable material, free from organic matter. The covering should be sufficient to prevent the contact of the water with the mud, peat or other organic material, and a depth of one foot will probably be sufficient in all ordinary cases. The covering should be extended beyond the edges of the peaty material so as to cover them liberally.

While no reservoir in the State has been prepared in exactly this manner, it seems altogether probable that the quality of the water in the reservoir, if treated in this manner, will be satisfactory.

Investigations of the present sources of supply of Leominster show that the yield, while somewhat indefinite, owing to leakage from Morse Reservoir, is probably between 850,000 and 900,000 gallons per day in a very dry season, an amount sufficient to supply between 90 and 100 gallons per day to each inhabitant. From investigations made by your engineer it appears that the amount of water actually used in the town in a summer month when observations were made exceeded an average of 180 gallons per inhabitant per day. This is an excessive consumption, as in all the cities and towns of the State where records of the quantity of water consumed are kept, excepting the city of Boston, the amount used in the year 1893 averaged less than 100 gallons per inhabitant, and in many towns of about the same size as Leominster the consumption per inhabitant was only from 40 to 60 gallons.

The quality of the water of your present sources of supply, with the exception of Haynes Reservoir, as shown by examinations of the Board in this and previous years, is excellent. The water of Haynes Reservoir has been of bad quality in the summer in every year in which it has been ex-

red by the Board. It is understood that a portion of the area covered the reservoir was originally swamp and meadow land, and after an additional supply has been introduced an investigation of Haynes Reservoir should be made to determine whether the quality of the water cannot be improved at reasonable cost; otherwise, it is desirable that the use of the reservoir be avoided except at such seasons, if any occur, when the quality of the water is not objectionable.

**LOWELL.** The water board of Lowell applied to the Board Nov. 1894, for its advice relative to the question of extending their driven-well system in the valley of River Meadow Brook in the town of Chelmsford. The Board replied to this application as follows:—

BOSTON, May 2, 1895.

It is learned from your annual report for 1894 that the average consumption of water during that year was 6,568,170 gallons per day, of which 4,272,617 gallons were pumped from the Merrimac River and the r-gallery and filter-bed beside it, and 2,295,553 gallons from the original driven-well plant, which was first used in September, 1893.

It is understood that the first driven-well plant was put in by you in order to substitute a pure water for the river water, and not because of any deficiency in the quantity of water to be obtained by the existing works in the river; and, as you are probably aware, the State Board of Health regards the river water, when not purified by filtration, as a dangerous water to drink.

As the first driven-well plant furnished a substitute for only a portion of the water formerly taken from the river, the new plant in the town of Chelmsford is now being constructed in order to obtain a substitute for at least a portion of the water which still has to be taken directly from the river.

Many analyses have been made from time to time of samples of water collected from the first driven-well plant, and, while there has been a slight deterioration during the past year, the water is of very good quality.

The new plant in the town of Chelmsford at the present time consists of a large number of wells driven on both sides of a long suction pipe, a short distance from and parallel with the old Middlesex Canal.

Six samples of water from these wells have been analyzed by the State Board of Health, five being collected under the direction of your city engineer and one by an engineer of the State Board of Health.

The first sample, collected on Jan. 24, 1895, was in every respect an excellent water. The second and third samples, collected respectively on March 4 and 20, had, after standing, considerable color for a ground water,

and contained more iron than is desirable in a water to be used for a public water supply, but in other respects were of good quality. It is understood that these samples were collected from the southerly half of the line of wells. The fourth sample, collected on April 3, from the northerly section of wells, was colorless, contained only an insignificant amount of iron, and was of excellent quality. The fifth sample, collected April 6, from a pump drawing water from 63 wells in the northerly and southerly sections, when 20 wells in the southerly section were shut off, had a scarcely perceptible color, contained a small amount of organic matter but more than any previous sample, and three times as much iron as the fourth sample but only about one-fourth as much as the second and third samples. The sixth sample, collected April 12, from the same pump, was of the same general character as the fifth sample.

The last two samples represent a larger number of wells than the others, and the water which they supply is of very good quality at the present time, but whether it will remain so when water is pumped continuously for a long time cannot be foretold with certainty with the present information.

Experience with the ground-water supplies in the State shows that in some cases the quantity of iron has increased and the waters have deteriorated in other respects with long-continued pumping, until it has become necessary to provide a new supply. In other cases the waters have remained unchanged after as many as twenty years of continuous pumping, but there is no case which has come to the attention of the Board in which long-continued pumping has improved the quality of the water.

Both the old and the new driven wells will derive a part of their supply by the filtration of water from River Meadow Brook, upon which the main village of Chelmsford is situated; and, while the water filtering from the brook in this way may become partially or wholly purified by its passage through the ground, the water of the brook should not be polluted by turning sewage into it.

The quantity of water drawn from the first driven-well plant during the year 1894 was 35 per cent. of the total quantity supplied to the city, and during the latter part of the dry portion of the year was a smaller percentage.

Judging from the quantities of water which have been pumped from the old and new systems of wells, and a careful study of all the conditions affecting the quantity of water to be obtained from them, the Board thinks it improbable that they will furnish more than half enough ground water in the drier portions of a dry year to meet the requirements of the city of Lowell; and the Board, therefore, urges you to proceed forthwith either to purify the water taken from the river or to obtain a further supply of pure water from some adequate source.

**MONTAGUE (MILLER'S FALLS).** The water supply committee of Miller's Falls applied to the Board Jan. 22, 1895, for its advice relative to the introduction of a public water supply for the village of Miller's Falls and the settlement known as Lake Pleasant by extending the pipes of the Turner's Falls water works. The Board replied to the application as follows : —

Boston, March 1, 1895.

Analyses of the water of this lake (Lake Pleasant) have been made at intervals for several years by the State Board of Health, which show that it is very soft and of excellent quality for water-supply purposes, and, with due care to protect it from pollution from the Lake Pleasant camp ground, it should remain of good quality.

It is not practicable at this season of the year, with the large amount of snow upon the ground, to determine how much water this lake will furnish. From such information as could be obtained, however, with the aid of the topographical map of the State, it seems probable that it will furnish a sufficient quantity of water for the village now supplied and the district which it is proposed to supply from it.

In view of all the circumstances, the Board is of the opinion that the proposed source of supply is an appropriate one for the villages of Miller's Falls and Lake Pleasant.

**MONTAGUE (VILLAGE).** An application was received Feb. 6, 1895, from W. H. Nims and others of Montague, requesting the advice of the Board relative to taking the water of certain springs about one-eighth of a mile south of the village as a source of public water supply for the village of Montague. The Board replied to this application as follows : —

Boston, Feb. 28, 1895.

It is understood that the water from the springs is to be collected into a small basin and well and pumped to an open distributing reservoir.

The Board has caused an examination of the source to be made, so far as was feasible at this season of the year, and an analysis of a sample of water collected from a brook flowing from the springs, and finds the water to be soft and in other respects of excellent quality for the purposes of a public water supply. If exposed to the light in open reservoirs the water is likely to be less satisfactory to the taste than if conveyed directly from the springs to the consumer, or stored in reservoirs from which the light is excluded.

The information in the possession of the Board is not sufficiently complete to enable it to predict whether this source will supply a sufficient

quantity of water for the village in a very dry season, but the indications are that it will do so.

**PAXTON.** An application was received from the selectmen of Paxton Jan. 29, 1895, for the advice of the Board relative to taking the water of Asnebumskit Pond as a public water supply for the town. The Board replied to this application as follows : —

Boston, Feb. 5, 1895.

The State Board of Health received from you on Jan. 29, 1895, an application relative to taking a water supply for the town of Paxton from Asnebumskit Pond, which is within the limits of the town, and on the same day received an application from the water commissioners of the Leicester water supply district relative to taking an additional water supply for Leicester from the same source.

The examinations made by the Board lead it to conclude that the water of this pond is of suitable quality for all the purposes of a public water supply, although it would be advisable to take first the water of certain springs at the southerly end of the pond to the extent of their capacity on account of the better quality of the water, and to supplement the supply from these springs with water taken from the pond.

The pond will furnish a sufficient quantity of water to meet the requirements of both communities, and, from its situation with relation to the town of Paxton and to the sources which at present supply Leicester with water by gravity, the Board regards it as an appropriate source of water supply for both places.

**PEPPERELL.** An application was received Oct. 10, 1894, from the water committee of the town of Pepperell, for the advice of the Board relative to the propriety of taking water for a public water supply from any source within the limits of Pepperell or from Rocky Pond in Hollis, N. H. The Board replied to this application as follows : —

Boston, Dec. 7, 1895.

The State Board of Health received from you on Oct. 8, 1894, an application with reference to a proposed water supply for the town of Pepperell, stating that permission would be asked of the Legislature to take water from any source within the limits of the town, and possibly from Rocky Pond in Hollis, N. H., if it should be high enough to furnish a supply by gravity. Subsequently a plan was submitted, indicating as the proposed source of supply a well near the Nissitissit River and just above the mouth of Sucker Brook in Pepperell.

A copy of a report by your engineer, relative to a water supply for the town, was submitted Feb. 8, 1895, proposing as a source of supply a collecting well to be located near the junction of the Nissitissit River and Sucker Brook, where it is thought that a considerable amount of water would be obtained from natural filtration through the ground from the river. A plan, which is understood to have accompanied the report of your engineer, was furnished by you in May, 1895. This plan indicates a collecting well near the Nissitissit River, just below the mouth of Sucker Brook, and a pumping station near the brook just above Brookline Street, and approximately 900 feet from the river. It is further stated in the report of your engineer, that, when required, a second smaller collecting well can be built farther up the brook in the Sartelle meadow, and the water carried by gravity to the proposed pumping station, a distance of about 7,500 feet; and it is suggested that in the trench in which the pipe to the Sartelle well would be laid a considerable amount of ground water would no doubt be encountered, and that this could be collected and taken in a tile pipe laid with open joints to the pumping station. It is further suggested that an additional supply might be obtained from the valley of Gulf Brook, above Smith & Willoughby's Pond, and delivered to the pumping station by gravity through a pipe 8,300 feet long.

The Board has caused a careful examination of the localities mentioned to be made by one of its engineers, and samples of ground water from a spring and a test well in the vicinity of the Sartelle meadow to be analyzed. The water of these samples was found to be of good quality except for its hardness, which would render it unsatisfactory for some of the purposes of a public water supply. No opportunity was found for obtaining samples of water from the ground near the mouth of Sucker Brook or in the valley of Gulf Brook.

With regard to the quantity of water to be obtained from the ground in the vicinity of the mouth of Sucker Brook by means of a well, as proposed, it is not feasible to make a definite statement, as no tests appear to have been made here to indicate the character of the soil; but, judging from the topography and the surface indications, the outlook appears to be very unfavorable to the existence of porous material beneath the surface here of sufficient depth and extent to yield enough water for the supply of the town.

The results of investigations made by you of the character of the soil in the vicinity of Sartelle meadow in the valley of Sucker Brook, by means of test wells, indicate that porous material is found beneath the surface here, from which water can be freely pumped, but that its depth is small, being in places less than 20 feet and nowhere exceeding 30 feet. The extent of the area of porous material has not been determined.

Farther down the brook, between the Sartelle meadow and Brookline

Street, in the region through which the pipe from the proposed well in the Sartelle meadow to the pumping station would be laid, test wells indicate that the material is a fine sand, from which it cannot be expected that any very large quantity of water can be collected by means of pipes laid with open joints, as proposed.

The investigations have not been sufficient to enable the Board to advise you definitely as to the probable quantity of water to be obtained from the proposed works in the valley of Sucker Brook, but with present information the indications are that the quantity of water which these works would furnish would not be sufficient for the supply of the town in the drier portion of a dry year, after water is generally introduced, and an extension of the collecting system would be necessary.

The investigations in the valley of Gulf Brook have not been sufficient to indicate definitely the character of the soil; but, judging from the information at present available, enough water might be obtained there to furnish, in connection with the proposed works in the valley of Sucker Brook, a sufficient supply of water for the town, though an extensive collecting system might be found necessary.

The situation of Rocky Pond in Hollis, N. H., beyond the limits of Massachusetts, must be regarded as a serious disadvantage to its use as a source of water supply for Pepperell. An analysis of a sample of water indicates that it is a water of good quality, and very soft. The area of the water-shed is not definitely known, but from present information it does not seem probable that the quantity of water which this source is capable of furnishing would be sufficient to meet the needs of the town after the water shall have come into general use.

From a general examination of other sources in the vicinity of the town, it is found that the surface indications in the valley of Unquetenasasset Brook appear to be favorable to the absorption by the ground of a large portion of the water falling upon its surface; and, before deciding definitely upon a source of supply, the Board would advise that you cause an investigation of the ground in the valley of this brook to be made, to determine whether an adequate supply of soft water and of good quality in other respects can be obtained from the ground here, and the probable cost of works as compared with those proposed for taking water from the valleys of Sucker and Gulf brooks.

The Board will, upon application, advise you further with regard to this matter when you have additional information to present.

PITTSFIELD (the Onota Water Company). The Onota Water Company in Pittsfield applied to the Board March 29, 1895, for its advice relative to the introduction of water for domestic purposes for that part of Pittsfield near West Street, the proposed supply to be taken

from a source or sources in the adjacent town of Hancock. The Board replied to this application as follows : —

Boston, May 2, 1895.

The Board has caused an examination of the proposed sources to be made by one of its engineers, and a sample of water from the brook to be first used has been analyzed. This sample was collected and the examination was made at a time of year when much water from melting snow was flowing in the brooks, and it was, therefore, impracticable to judge accurately of the quantity or quality of the water during seasons of low flow.

The sample of water was found by analysis to be of excellent quality and to be soft, and, judging from the character of the water-shed, which is uninhabited, the water will be of good quality at all seasons of the year, though it will probably be harder during seasons of low flow than at the time the sample was taken.

The measurements which you have made of the dry-weather flow indicate that this source may furnish at all times an ample supply of water for the small population to be supplied from it at the present time, and, should it prove insufficient in the future, it seems feasible to enlarge the capacity of this source by building a storage reservoir or to obtain an additional supply from other brooks flowing down the easterly slope of these mountains.

The Board, therefore, regards the sources proposed by you as appropriate ones from which to take a water supply for the inhabitants of the high lands in the westerly portion of Pittsfield.

**READING.** An application was received from the water board of Reading March 15, 1894, for the advice of the State Board of Health relative to the purification of the public water supply of the town. The special points upon which information was desired, together with the reply of the Board, are indicated as follows : —

Boston, Feb. 18, 1895.

The State Board of Health received from you on March 15, 1894, an application asking for its advice with reference to a proposed system of purification for the water supply of the town of Reading, in which you state that your proposed additions are fully set forth on page 24 of your report for 1894. You further state that "The water board of Reading are anxious to ascertain from the State Board of Health : —

"*First.* — Whether the State Board has any suggestions to make as to the advisability of adopting the above system.

"*Second.* — Whether the State Board has any facts in its possession which will aid the water board of Reading in arriving at the best solution of their water troubles.

“*Third.*— Whether the State Board has any recommendations to make as to abandoning the present supply and seeking a new source.

“*Fourth.*— Whether, all things considered, the treatment in the method proposed is not the best thing that the town of Reading can do.”

About one month later the Board received from the committee on water supply of the town of Reading a communication requesting the Board to examine the territory around the source of the Mystic River, with a view to a supply for Reading from that source, and to examine Silver Lake in Wilmington for the same purpose.

This application received the attention of the experts of the Board soon after it was submitted, but, owing to the nature of the advice asked for, it was necessary to determine the probable effect of the proposed treatment of the water at times when the meadow in which the filter-gallery is situated is covered with water, which did not occur until about the 20th of October.

A very large number of examinations of the water of the filter-gallery have been made during these investigations and previously, and from these results it appears that the objectionable character of the Reading water is due chiefly to the presence at nearly all times of an excessive amount of iron, in connection with other mineral and organic matter. The amount of iron found in the water varies greatly at different times, being very large in the portion of the year when the meadow is covered with water and much smaller during the summer when the meadow is dry. It has also been observed that the quantity of iron present in the water may vary greatly in the course of a single day's pumping.

In contrast with other waters in which a sufficient amount of iron has been found to affect the appearance and quality of the water, it has been found that the iron in the Reading water is present as a sulphate instead of being in the form of bicarbonate. When iron is present as a sulphate its removal from water is very much more difficult than when it is present as a bicarbonate.

Many experiments have been made at different times, with a view to a removal of the iron by oxidation and subsequent filtration of the water through sand to remove the precipitated iron oxide. The results obtained by this means have been very variable. But in general it may be said that when the iron is present in the water in small amount, say not over 0.3 of a part per 100,000, the iron will separate out of the water almost completely on exposure to the air for twenty-four to thirty-six hours, in the form of a rusty precipitate which can be removed entirely by filtration through sand at a rapid rate. This method is substantially that proposed by Mr. Desmond Fitzgerald in his report to your board. Forced aeration by filtering through sand with a current of air was found in almost all cases to hasten the oxidation and separation of the iron oxide.

But in one case at least, when the iron was only 0.14 parts per 100,000, aeration in this way had but little effect on the iron. The failure to remove the iron in this case seemed to be connected with a considerable amount of organic matter in the water, which prevented the precipitation of the iron after oxidation.

Again, the difficulty in removing the iron appears to increase rapidly with the amount of iron in the water, and when large amounts are present, say from 1 to 2 parts per 100,000, which has been frequently the case the past winter, the means found adequate to remove the iron when present in small amounts are unavailing. Exposure to the air for two days had practically no effect on the iron contents of water of this character, and even after thorough aeration it separated out only in part, leaving most of the iron still in the water, upon which filtration had no effect.

During the progress of this investigation, advantage has been taken of the presence at the Reading pumping station of a small mechanical filter placed there and first operated about the middle of the summer. This filter consisted of two upright cylinders, one said to contain 30 inches in depth of sand, and the other 30 inches of bone-char, each having an area of about one square foot. Later in the season the number of cylinders was doubled.

Experiments with this filter showed that with iron not exceeding 0.1 of part per 100,000, rapid filtration alone without exposure to air was capable of removing practically all of the iron in the water, but when the water contained larger amounts of iron the action of the filter was uncertain. With very high iron, say 1 part per 100,000, the filter had no effect whatever on the amount of iron. No special advantage was found in the use of bone-char in these experiments, and it is, therefore, probable that any sand filter capable of being readily and thoroughly cleaned would do equally good work.

Any treatment by filtration which will remove the iron will be very likely also to remove the objectionable odor and appearance of the water.

When the amount of iron in the water was very high, experiments were made to learn whether it could be removed by chemical means, a cheap form of which would be filtration through carbonate of lime (in the form of marble chips). The experiments in this line have indicated that the iron can be completely removed by filtration through carbonate of lime, but that in this process the water takes up lime in large amount, and is made very hard. A combined process of aeration and filtration through sand and with subsequent filtration through carbonate of lime leaves the water much less hard than when it is put directly upon a filter containing marble; and the results indicate that the hardness of the water after treatment in this way could be at least 16 to 18 parts per 100,000, while the hardness of the

water after filtration through carbonate of lime, without previous aeration and filtration through sand, is likely to be at least 25 parts per 100,000.

While the hardness of the water, if treated chemically, by filtration through carbonate of lime as suggested, would be very little or no greater than that of waters supplied to some of the towns in the vicinity of Boston, the Board does not recommend the use of so hard a water for a permanent supply.

Since the higher amounts of iron and organic matter are found when the meadow is flooded, it would seem that the quality of water in these respects might be greatly improved and the water rendered more susceptible of further improvement by filtration or other treatment, if this flooding were prevented.

The artificial flooding could be prevented by keeping the gates at the dam open, but this might not prevent the flooding of the meadow during periods of very high flow in the stream; but this flooding would be of short duration, and would not affect the quality of the water nearly as much as the present flooding, which lasts for many months. The flooding could be wholly prevented by building dikes.

Examinations of the ground in the vicinity of the Ipswich River, between one and two miles above your present works, by means of test wells driven by your Board, were favorable in respect to quantity; but the water of the wells was found on analysis to contain so much iron that its quality would be likely to be unfavorably affected from this cause, if a supply should be taken from the ground in this locality. A similar examination in the water-shed of Lake Quannapowitt, south-east of the village and near the Wakefield boundary, gave similar unfavorable indications as to the quality of the ground water to be obtained in that region.

A sample of water collected from a tubular well located in the area known as the Bancroft meadow was found on analysis to be of excellent quality; but the area from which water drains toward this meadow is so small that it is improbable that any large supply of water could be drawn continuously from this source.

Other territory within the limits of the town was examined, but at no place were the surface indications sufficiently favorable to afford a reasonable expectation that a supply of water of satisfactory quality and in sufficient quantity for the supply of Reading could be obtained.

The right to a supply from Martin's Pond has already been granted to the city of Malden, and the Board has already stated, in a reply to that city (annual report for 1892, page 28), that it does not consider it feasible to obtain a satisfactory supply directly from this pond. Investigations made recently by that city with a view to taking a supply from the ground in the vicinity of this pond have been unfavorable, and at the present time

it does not seem probable that Malden will build works for taking its supply from this source.

A supply from the head-waters of the Mystic River would have to be taken above the chemical works near South Wilmington, in order to avoid danger of pollution from those works. The water-shed here is too small to furnish a sufficient supply without storage, and there appears to be no good site for a storage reservoir of sufficient size; moreover, this territory is within the Mystic water-shed, which is inadequate for the supply of the cities now supplied from it.

No investigations of the ground at this place have been made, but, owing to the small size of the water-shed, the conditions beneath the surface would need to be exceptionally favorable to obtain any considerable amount of ground water from this source.

Silver Lake, in Wilmington, has an area of about 32 acres and a very small superficial water-shed. It may, however, yield more water than is indicated by the size of its water-shed, because it is surrounded by extensive areas of sandy soil.

Judging from the surface indications and from the character of the material obtained from two test wells driven in the vicinity, it is not improbable that investigations would show that enough good water might be gained from the lake or from the ground in the vicinity of the lake or of Upper Brook, which flows very near it, to supply Reading and Wilmington; but the amount and quality of the water can only be determined with certainty after the ground has been thoroughly tested and samples of the water examined.

As you are aware, the State Board of Health has recently submitted to the Legislature a report upon a general system of water supply for the metropolitan district about Boston; and, while Reading is situated outside the ten-mile limit referred to in the act under which this report was made, there seems to be no reason why it may not be included among the places to which this supply is to be furnished.

No data are at hand upon which to base a definite estimate of the probable cost of works for the supply of Reading from Silver Lake; but the likely cost of obtaining a supply from this source would probably exceed considerably the cost of a supply as a part of the metropolitan water district.

With its present information, the Board advises the town of Reading to take measures to obtain its future supply as a part of the metropolitan water district, and to abandon its present source when the new supply becomes available. In the mean time, provision should be made to improve the present supply by preventing the flooding of the meadow over the outfall-gallery, and it may be advisable to adopt, temporarily, some system of filtering the water rapidly through sand.

**RUTLAND.** The committee on water supply of the town of Rutland applied to the Board Dec. 24, 1894, for its advice relative to taking the water of Lake Muschopauge in that town as a source of water supply for the town. The Board replied to this application as follows : —

Boston, Feb. 23, 1895.

The examinations made by the Board lead it to conclude that this pond will furnish a sufficient quantity of water of suitable quality for all the purposes of a public water supply, and that it is, therefore, an appropriate source of supply for the town.

**SHEFFIELD.** H. S. Andrews and others of Sheffield applied to the Board Nov. 20, 1894, for its advice relative to taking the water of certain springs in that town, about two and one-half miles north-east of the village, as a public water supply for Sheffield. The Board replied as follows : —

Boston, Feb. 23, 1895.

It is understood that it is proposed to intercept the flow from springs, and to store the water in small reservoirs from which it will flow by gravity to the portions of the town to be supplied.

The samples of water collected from the springs early in January, 1895, have been found by analysis to be very soft, and of excellent quality for the purposes of a public water supply. If exposed to the light in open reservoirs the water is likely to be less satisfactory to the taste than if conveyed directly from the springs to the consumer, or stored in reservoirs from which the light is excluded.

With regard to the quantity of water, it is not feasible to tell with certainty from the present information whether or not a sufficient supply can be obtained from the springs, but the prospects are favorable ; and, if the supply should prove insufficient during a portion of the year, it appears probable that it might be supplemented from a small brook which flows near the springs, by constructing a storage reservoir upon it above them.

The Board regards this source as an appropriate one from which to take a supply of water for the town.

**SHIRLEY.** An application was received Nov. 5, 1895, from the selectmen and committee on water supply of the town of Shirley, for the advice of the Board relative to taking water from Leatherboard Pond in that town as a public water supply. The Board replied to this application as follows : —

Boston, Dec. 5, 1895.

The quantity of water which the proposed source is capable of furnishing is ample for the use of the inhabitants of the town of Shirley. With regard to quality, however, the water of this source would be very unsatisfactory, owing to its high color and unpleasant odor, as indicated by a sample collected Nov. 13, 1895, due to its contact with vegetable matter in the large swampy area within the water-shed of Bow Brook above the point where it enters the pond. The character of the pond itself, moreover, is not such as to influence favorably the quality of the water, as it is very shallow, and the bottom appears to be covered in places with mud and vegetable matter. The quality of the water may also be greatly influenced from time to time by the condition of the water in Fort Pond, situated near the upper end of the water-shed of the brook. This pond is used as a storage reservoir, and its water is drawn off during the drier portion of the year through Leatherboard Pond, to assist in maintaining the flow of the stream below. A sample of water, collected from Fort Pond November 13, contained a very large number of organisms, mostly of a kind which is liable to produce offensive tastes and odors, and this water in its present condition would be very unsatisfactory for domestic purposes. It is not feasible to tell whether the water at the present time is better or worse than at other seasons of the year, but it may be said that as a rule the quality of the water of ponds is worse in summer.

In view of the poor quality of the water of Leatherboard Pond and the unfavorable character of its water-shed, the Board does not advise its adoption as a source of water supply for the town of Shirley.

While the Board is not fully informed as to the feasibility of obtaining a satisfactory supply from some other surface source in the vicinity of Shirley Village, it seems probable, with present information, that a ground-water supply of good quality, if such a one can be obtained, would be more satisfactory for the town than any surface-water source in the vicinity; and the Board advises that it is desirable in making further investigations for a water supply, to determine the feasibility of obtaining a satisfactory supply in this way, but cannot with present information advise definitely as to the place for making investigations.

The Board will, upon application, advise you further in this matter when it has the results of further investigations to present.

STOUGHTON. An application was received from the Stoughton Water Board Jan. 16, 1895, for the advice of the Board relative to producing a supplementary supply of water, in accordance with the methods and plans presented by their engineer. To this application the Board replied as follows:—

BOSTON, April 4, 1895.

One of these plans provides for collecting the water of the springs which outflow at the edge of the low land surrounding Muddy Pond, and is, in its general features, the plan recommended by the State Board of Health in its communication to you dated Oct. 13, 1893, a copy of which is enclosed herewith. The other plan provides for taking water from a well located about 1,150 feet above the present pumping station, on a point of land at the junction of Muddy Brook and the brook flowing from Stoughton village.

In choosing between these two plans, the most important features are, obviously, the quantity and quality of water which they will furnish.

With regard to the quantity of water which the first plan will furnish, it may be said that the communication above referred to stated that the total flow of the springs, as represented by the outflow from Muddy Pond on April 26, 1892, was 1,410,000 gallons per day, and on Sept. 11, 1893, fully 1,000,000 gallons per day. Measurements made under the direction of your engineer from Sept. 24 to Oct. 4, 1894, show that the flow ranged from 435,000 to about 900,000 gallons per day. A measurement made on March 15, 1895, showed that the amount was upwards of 1,500,000 gallons per day. The lowest of the above quantities is considerably more than enough for the present population of the town, with any ordinary rate of consumption of water per inhabitant; but it is enough smaller than the other measurements to indicate the possibility, under extreme conditions, of an insufficient flow from the springs, making it necessary to have recourse to some surface-water or other supplementary source at such time. Of the excellence of the water to be obtained from this source there is no doubt, provided it is intercepted, as advised in the last communication, before the water has been exposed to the light or come in contact with the vegetable matter in the swamp surrounding the pond.

The tests made near the site of the well proposed by the second plan show that there is a thick layer of porous gravel underlying the fine sand found for a considerable distance down from the surface, and from the gravel water can be pumped very freely. Judging from the freedom with which the water can be pumped from several of the test wells, there seems to be no doubt that when the ground is full of water a well or wells at this place will furnish it at a rate sufficient for the supply of the town, and the question of a supply from this source depends mainly upon whether there will be a gradual lowering of the water in the ground during dry seasons, with a corresponding diminution in the amount of water which can be pumped from the well.

From all the information now available, it seems probable that the springs at Muddy Pond will furnish more water both in wet and in dry seasons than the proposed well.

ample of water collected from one of the test wells near the site of proposed well was analyzed and found to be of excellent quality, but sample does not necessarily indicate the quality of the water to be obtained by continuous pumping from the well. It does not seem at all probable that the well will furnish a sufficient quantity for the supply of the town unless the water in it is drawn below the level of the adjacent millpond and a considerable amount of water filters from this millpond and seeps further up the stream coming from the village to maintain the level of the ground about the well. The water filtering in this manner is thoroughly purified by its passage through the ground to the well; this is somewhat uncertain, and the filtration would not soften the water of this stream, which is hard, owing to its pollution. For both of these reasons the water to be obtained from the well must be regarded as inferior in quality to the unpolluted spring water.

If the plan for taking water from the springs were to be adopted, it would be desirable, unless an abundant supply of water was developed by extending a pipe to the point indicated by your engineer, to extend it still farther, so as to intercept the springs entering the pond from the easterly side and throughout the territory where the springs outflow it is desirable that the line of the pipe should be moved in toward the foot of the high ground, by so doing quicksand and mud can be avoided, and the trench dug in a more porous, gravelly material. It would also be advisable, as suggested in the last communication, to lay smaller branch pipes to tap the spring water at the places where it outflows in the greatest quantity.

In addition to the proposed well, the plan recommended by your engineer is for the construction of a small reservoir just above the Southworth mill now owned by the town, on Muddy Brook, which would have some value particularly when first constructed, upon the amount of water to be obtained from the proposed well, and the reservoir is also intended as a secondary source from which to take water directly if the supply from the well should prove insufficient. If the supply were to be taken from the springs, the pipe leading from them would pass near and below the level of the Mill Pond, from which water might be taken in a very dry time if the supply from the springs should prove insufficient; or, if it should be deemed desirable to have a large quantity of water in reserve near the pumping station, such a reserve could be provided in connection with the plan for taking water from the springs as well as in connection with the other plan. Reference is also made in the report of your engineer to the expediency of procuring a supplementary or an independent supply of water from Knowles

Owing to the fact that your pumping station is located in the valley of Muddy Brook, and the probability that a larger supplementary supply of excellent water can be obtained from the valley of this brook

than from Knowles Brook, it seems clearly undesirable at the present time to take the additional supply from the latter source.

**WALPOLE.** The water commissioners of Walpole applied to the Board March 29, 1895, for its advice relative to the introduction of a public water supply from the ground in the valley of Low Brook, about one-half mile above its junction with the Neponset River. The Board replied as follows : —

Boston, June 7, 1895.

The subject of a water supply for Walpole was brought to the attention of this Board by an application of the committee on water supply of the town in 1893, and the Board on June 5 of that year made the following reply : —

“ The investigations made near the Neponset River, not very far above the Blackburn water privilege and just below Low Brook, showed very satisfactory results as regards the porosity of the material, the freedom with which water could be pumped from the test wells and the quality of the water. Taking these results in connection with an examination of the surrounding territory and the size of the streams, the Board finds no reason to doubt that an ample supply of excellent water can be obtained from a well or wells located in the porous material in this vicinity.”

Judging from the tests which you have made by driving wells and pumping from them at the source now proposed in the valley of Low Brook, the results at this place are also very satisfactory as regards the porosity of the material and the freedom with which water could be pumped from test wells, and analyses show that the water is of excellent quality. The watershed and streams which must be depended upon for maintaining the saturation of the ground at the new location are much smaller than at the former one near the Neponset River, and, judging from all of the information at present available, the source near the Neponset River would be likely to furnish the larger quantity of water. It is not improbable, however, that wells at the new location would supply the town with all of the water required for ordinary water supply purposes for several years; but if, as has been suggested, large quantities of water are to be supplied for manufacturing purposes, the source now proposed would probably prove inadequate.

There is uncertainty, in nearly all cases where water is to be taken from a ground-water source, as to just how much water the source will furnish at the end of a long-continued drought; and, as it is very desirable that you should obtain as large a quantity of ground water as possible, the Board advises you, before finally locating your wells and pumping station, to make further investigations, with the aid of an engineer skilled in the

ction of ground-water supplies, having in view the location of the works be place where the largest quantity of water of satisfactory quality can obtained, either from the original works or from extensions to be made sequently.

VENHAM. An application was received from the selectmen of nham, Feb. 18, 1895, for the advice of the Board relative to ing the water of Pleasant Pond in that town as a source of public er supply. The Board replied to this application as follows: —

Boston, March 25, 1895.

he Board has caused an examination of this source and an analysis of mple of water collected from the pond near its outlet to be made. s pond will furnish an abundant supply of water for your town, and the er is of fair quality, but not as good as it is desirable to introduce into town if a better water can be obtained.

he unsatisfactory character of the water is due to the surface drainage n the streets in a portion of the village, the drainage from a small mp south of the main street and much larger swampy areas south of pond, and the percolation of polluted waste water from a portion of village through the ground into the pond or its feeders.

as suggested by one of your board that most of the street wash e referred to, and the drainage from the small swamp south of the t street, might be diverted from the pond and made to flow in a south-direction to Miles River; and this would have a tendency to improve quality of the pond water, but it would not be likely to make enough ge in the quality to make the water wholly satisfactory.

a public water supply were introduced from any source, without at ame time providing a system of sewers, there would be more polluted e water turned into the ground than at present, and more would find ay by percolation or otherwise into Pleasant Pond. These waters, if thoroughly purified by percolation through the ground so that they l not be dangerous to health, contain soluble matters which would ote the growth of the minute organisms which frequently give waters l in ponds and reservoirs a disagreeable taste and odor.

s possible that investigations may show that a water which is entirely actory in quality can be obtained from the ground near the pond, or some other ground-water source within the limits of the town. The

also calls attention to the fact that the pumping stations of the water of Beverly and Salem are but little more than a mile and a half from tre of Wenham village; and if arrangements could be made whereby ities or either of them would furnish water at a small advance upon

its cost, the water would probably cost the town of Wenham much less than if obtained by the construction of independent works.

The Board will advise you further in this matter, if you so desire, when you have further information to present for its consideration.

**WESTFIELD.** The committee on additional water supply of the town of Westfield applied to the Board Jan. 28, 1895, for the advice of the Board relative to the taking of Munn Brook in Granville at a point near its junction with Tillotson's Brook, as an additional source of water supply for Westfield. The Board replied to this application as follows : —

Boston, Feb. 6, 1895.

The water commissioners of the city of Holyoke applied to this Board on June 13, 1893, and again on Jan. 18, 1894, for its advice relative to taking an additional water supply from this source, and the replies of the Board to these applications are transmitted herewith. You will find in them the opinion of the Board with regard to the quality of the water so far as it has information up to the present time.

The city of Holyoke is in urgent need of an additional water supply, and the Board has in one of the replies expressed the opinion, which it still holds, that Munn Brook is the most appropriate source from which to take an additional water supply for the city of Holyoke; but the Board also believes that the brook is an appropriate source of additional supply for the town of Westfield, provided it is taken jointly by the two communities. The construction of works for the joint supply of the two communities would materially lessen the cost to each, if arrangements were made for an equitable division of their cost; and, although the capacity of the source would be reached sooner if it were used by the two communities than by either one, it will continue, with proper development by the construction of storage reservoirs, to supply both for a considerable time, and the supply can be supplemented from the Westfield Little River in the future if the supply from Munn Brook should prove insufficient.

The Board, therefore, advises you to consider the question of obtaining an additional supply from this source in connection with the city of Holyoke.

**WESTON.** Charles H. Fiske and others, petitioners for incorporation as the Weston Water and Electric Company, applied to the Board April 30, 1895, for its advice relative to taking a water supply for the town of Weston from springs in the neighborhood of Central Avenue in that town. The Board replied to this application as follows : —

Boston, Aug. 2, 1895.

The analysis of water from the test wells nearest Central Avenue showed it had at some time been polluted and subsequently well purified by its passage through the ground, while the analysis of the water of one of the wells on the farther side of the meadow from Central Avenue showed only a slight trace of previous pollution and a very thorough purification of the water by its passage through the ground. This water, as it came from the ground, except for a slight turbidity which would disappear after the wells were in constant use, was of excellent quality for all the purposes of a public water supply; but it is not improbable that the continuous draught of water from the ground at this place would cause the water which stands upon the meadow to filter downward, thereby making the water less attractive and palatable, and causing it to take up enough iron to render it unsuitable for drinking purposes.

The Board, therefore, advises you, before putting in works in this vicinity, to make further tests by driving wells in the low, sandy land lying between the meadow and the railroad; and, if these tests should show the existence of pervious material from which water of good quality can be pumped freely to a depth of 25 feet or more below the level of the meadow, it would then be advisable to locate the wells in the hard ground far from the meadow as possible, as the water obtained in this way would be much less likely to deteriorate than if the wells were sunk in the saturated meadow.

The Board will advise you further in this matter, if you so request, after additional tests have been made.

**WILLIAMSTOWN.** The Williamstown Water Company applied to the Board Sept. 16, 1895, for its advice relative to taking Flora en Brook as an additional source of water supply for that town. The Board replied to this application as follows:—

Boston, Oct. 23, 1895.

The Board has caused the proposed source of supply to be examined by one of its engineers, and a sample of the water to be analyzed. The analysis indicates that the quality of the water is excellent, and its hardness much less than that of the water of Sherman Spring and only about one-third of that of the water of Cold Spring, your present sources of supply. With the amount of storage proposed, a large addition to your present supply can be obtained from this brook, and, with properly prepared reservoirs, the quality of this water is likely to be more satisfactory to consumers than the water of either of the two springs now used as sources of supply, on account of its comparative softness.

It is improbable that your present and proposed works together will furnish as much water as ought to be provided for a growing town like Williamstown; and the development of small sources, that are likely to prove inadequate in a very few years if the town continues to grow, or if there should be a large increase in the use of water, is not in the interest of true economy. The Board would, therefore, advise that, before making further additions to the works, you have a thorough investigation made, with a view to determining the best source for the permanent supply of the town.

**WINCHENDON.** The committee on water supply of Winchendon applied to the Board Jan. 31, 1895, for further advice in regard to the Prentiss meadow in that town as a source of water supply for the town. The Board replied to this application as follows: —

Boston, May 15, 1895.

The State Board of Health received from you an application dated Jan. 31, 1895, for further advice with regard to the Prentiss meadow as a source of water supply for your town, and with this application you have submitted a report of your engineer, giving the results of certain pumping tests and investigations which have been made in order to determine the capacity of this source.

The water supply of Winchendon has been the subject of careful consideration by this Board on several occasions, and your attention is again called to the replies made by the Board to your committee on February 17, April 6, August 3 and September 10 of last year, for a general consideration of the subject of the water supply for your town and an extended consideration of the Prentiss meadow source, concerning which you now ask further advice.

Before referring to the reconsideration of the subject with the aid of the new information furnished, it may be well to state that the reply of the Board, dated Sept. 10, 1894, after referring to a method of estimating the quantity of water to be obtained from a ground water source, stated: "Upon this basis the engineers of the Board have estimated that a well or wells in the Prentiss meadows would yield during the driest four months of a dry year about 130,000 gallons per day." Again, after calling attention to the fact that the capacity of a ground-water supply cannot be determined with nearly as much accuracy as of a surface-water supply, the further statement was made: "While, therefore, the Board estimates that the quantity of water to be obtained from a well or group of wells in the Prentiss meadow would be from 100,000 to 200,000 gallons per day, it cannot be at all definitely stated that the quantity may not be even more or less than these figures."

From the information contained in Mr. Fuller's report and additional

on furnished directly by him, it is learned that one test was made day and night for thirty-seven days, from a well about 20 feet about 8 or 9 feet in diameter at the bottom. This test began on and ended on Oct. 10, 1894. During rather more than the first test no measurements of the quantity of water pumped are but it is stated that the flow was probably somewhat more than during fourteen days when the measurements were taken. The water was kept pumped down to within one foot and nine inches of the bottom of the well, so that the quantity pumped represented substantially the water which the well would furnish. The average quantity pumped per day during the last fourteen days was 271,000 gallons, and there was a gradual lowering of the water in the ground in the vicinity of the well.

A second test was made by pumping for seventeen days, from Dec. 19, Jan. 4, 1895, from ten driven wells, the nearest of which was 100 feet from the dug well, and during the last three and a half days at least water was also pumped from the dug well. The amount of water pumped from the driven wells averaged 245,000 gallons per day, but there was a very large reduction in the quantity pumped per day during the last few days of the test. The dug well supplied an average of 296,000 gallons per day during three and a half days, but even in this short time there was a noticeable reduction in the amount of water pumped. At the end of this test the water in the dug well rose to its normal level more slowly than after the first one.

In interpreting the results of these tests, it is necessary to take into account the rainfall at and before the time when they were made and the condition of the year as affecting the proportion of the rainfall, which was able to soak into the ground and aid in maintaining the supply during the

interim. The rainfall at Winchendon during the first test, as reported by the Bureau, was 8.66 inches, and during the second test 1.26 inches. The rainfall during the last four months of the year, as compared with the rainfall in Massachusetts during the same months and with the rainfall in a very dry year, is given in the following table:—

| MONTH.          | Rainfall at Winchendon, 1894 (Inches). | Average Rainfall in Massachusetts (Inches). | Rainfall in a Very Dry Year (Inches). |
|-----------------|----------------------------------------|---------------------------------------------|---------------------------------------|
| Feb. . . . .    | 7.09                                   | 3.81                                        | 1.60                                  |
| Mar. . . . .    | 2.63                                   | 3.87                                        | 3.74                                  |
| Apr. . . . .    | 2.06                                   | 3.96                                        | 1.78                                  |
| May . . . . .   | 3.25                                   | 3.57                                        | 2.83                                  |
| Total . . . . . | 15.03                                  | 14.71                                       | 9.95                                  |

The table shows that the tests were made during months when the rainfall was, on the whole, slightly above the average. The season of the year also has an important bearing, because during the warmer months the greater part of the rain which falls goes off again into the air by evaporation, while in the cooler months of the year, until the ground is solidly frozen, a much larger proportion remains to soak into the ground. A large allowance, therefore, has to be made, in order to insure an unfailing supply, to offset the diminished yield during seasons of lower rainfall and during the warmer portions of the year when more water evaporates. It should also be noted that, even during the season of comparatively large yield when the tests were made, the water in the ground continued to lower, and with continuous pumping for a much longer time it is probable that the wells would have yielded less water than they did during these comparatively short tests.

The estimates of the capacity of a well or wells at this place, as formerly made by the engineers of this Board, related to the yield during the driest four months of a dry year, and were based in part upon the exhaustion by long-continued pumping of the water stored in the ground in the vicinity of the wells; and, now that the tests have been made, we are unable to conclude that the quantity of water obtainable under these conditions would exceed the amount originally estimated, — an amount too small to supply the town after water shall have begun to be generally used.

Your engineer suggests in his report that the ground surrounding the wells may be kept saturated by introducing water from the river by means of drain pipes with open joints, placed as much as 100 feet from the wells. The Board regards this method of supplementing the supply as an impracticable one, mainly because the matters strained out of the river water would accumulate where the water passes from the joints of the pipe into the ground; and, as they could not be removed, the filter would before long become clogged and inoperative.

The Board, in its former investigation of this subject, considered various methods of extending the collecting system and maintaining the saturation of the ground by water taken from the river, and, after indicating methods which might be adopted, made the following statement: —

“Taking into account the first cost of this complicated system of works, the yearly cost of operating them in such a way as to obtain a sufficient supply of good water and the uncertainty as to the results which would be obtained, it does not seem advisable to adopt this plan, when you may obtain from Upper Naukeag Pond, by a simple plan and probably with a much smaller annual cost, an ample supply of water of good quality.”

Since the Board, after a careful consideration of all of the information furnished by your extended investigations, does not have occasion to modify its former estimates as to the probable capacity of a well or wells

the Prentiss meadow, or to change its conclusions with regard to supplementing the supply to be obtained from the ground at this place, it has no occasion to modify the advice already given to you with regard to this source of water supply.

All of the analyses of water from Upper Naukeag Pond show it to be of better quality for water-supply purposes than the water usually obtained from ponds. Six years ago the water had a disagreeable odor, such as has been found occasionally in nearly all of the surface-water supplies of the State, including some of the best ponds; but this odor, though disagreeable, is not known to be injurious to health. No trace of the odor has been found in the water of Upper Naukeag Pond for six years; and, with the results of your investigations in view, the Board is unable to advise that there is within your reach any other source as desirable as this.

In response to the request contained in a communication dated March 6, 1895, the Board sends herewith analyses of samples of water collected from different sources near Winchendon during the past year, with a brief statement of the quality of the water from each source, as indicated by the analyses.

The analyses sent included four from upper Naukeag Pond, — Nos. 12095, 792, 13813, 14122; two from Prentiss meadow, — No. 12188, driven well No. 3, No. 13092, dug well; one from Miller's River, opposite Prentiss meadow, No. 12187; one from Beaman Brook, No. 12094.

These analyses show that the waters of Upper Naukeag Pond and the wells in the Prentiss meadow are soft and of excellent quality for all the purposes of a public water supply.

The waters of Miller's River opposite the wells and of Beaman Brook have a deep brownish color, such as water acquires from contact with vegetable matter in swampy places, contain considerable organic matter, and would not be of satisfactory quality for drinking and some other water supply purposes.

**WORCESTER.** An application was received Feb. 21, 1895, from the mayor of Worcester, for the advice of the Board relative to the condition of the water of Kettle Brook to the existing water supply of the city. The Board replied to this application as follows: —

Boston, March 2, 1895.

The State Board of Health received from you Feb. 21, 1895, an application for its advice relative to the proposed additional water supply for the city of Worcester, to be obtained from Kettle Brook, at or near Kent's Falls, and diverted into the existing Lynde Brook Reservoir, from which the high-service supply of the city is now taken.

The Board has caused examinations of this brook to be made and samples of water from it to be analyzed, and it finds that the water as it now runs in the stream is of fair quality and likely to be as good after storage in the Lynde Brook Reservoir as the water now supplied to the city from that source. The water can be improved, however, by ceasing to use the Arnold Reservoir, which floods a swampy territory near the head of Kettle Brook to a small depth, by draining this swampy territory and by other methods of improving the quality of the water which will suggest themselves to your engineers.

This brook will furnish by gravity a substantial addition to the present supply of your city at a very small cost for engineering works, and the Board regards it as an appropriate source from which to take the next addition to the water supply of your city.

WRENTHAM (PLAINVILLE). An application was received Jan. 8, 1895, from H. G. Bacon and other citizens of Plainville in Wrentham, for the advice of the Board relative to taking the water of Ten Mile River, at some point above Plainville, to which the Board replied as follows: —

Boston, Feb. 5, 1895.

The State Board of Health received from you on Jan. 8, 1895, an application for advice relative to a proposed water supply for a part of the town of Wrentham, in which you state that it is your intention to introduce a system of water supply in the village of Plainville in the town of Wrentham, and, for the purpose of carrying out such a plan, a petition will be presented to the General Court. You ask for advice upon the proposed plan to take the water of Ten Mile River at some point between the village of Plainville and the head of Ten Mile River.

The Board, under date of Dec. 20, 1894, advised the board of water commissioners of the town of North Attleborough with regard to the Ten Mile River above the village of Plainville as a source of water supply for the town of North Attleborough and the village of Plainville. In the communication to North Attleborough (a copy of which is published in the twenty-sixth annual report of the State Board of Health, 1894, page 35), you will find the opinion of the Board with regard to the quality of the water; also its opinion as to the propriety of taking water from this source for the supply for the village of Plainville, as well as for a supply for the town of North Attleborough.

#### SEWERAGE AND SEWAGE DISPOSAL.

The following is the substance of the action of the Board during 1895, in reply to applications for advice relative to sewerage and sewage disposal: —

**AMESBURY.** An application was received from the committee on sewerage of the town of Amesbury Nov. 2, 1894, for the advice of the Board relative to the sewage disposal of Amesbury, having proposed outlets into the Powow River. The Board replied to this application as follows : —

Boston, Feb. 12, 1895.

The State Board of Health received from you an application dated Nov. 1894, in which you ask its advice with regard to the disposal of the sewage of Amesbury, and with this application you submit certain plans made several years ago and suggest that they will require some modification.

The Board advises that you have the whole subject re-examined and plans prepared for discharging the sewage into the Merrimack River, and that you adopt a plan for disposing of the sewage in this manner, if it is found practicable to do so. If, however, you find that the cost is too great to warrant the adoption of the complete plan at the present time, it is permissible to discharge temporarily into the Powow River at or below the mouth of Patten's Brook as much sewage as will be furnished by a population of 5,000, but the outlet pipe should be extended to deep water, so as to avoid fouling the shores.

**ANDOVER.** An application, submitting certain specific questions, was received from the sewer commissioners of Andover, Aug. 1, 1895, for the advice of the Board relative to two plans of sewerage and sewage disposal for that town. The Board replied to this application as follows : —

Boston, Oct. 10, 1895.

The State Board of Health received from you on Aug. 1, 1895, an application with reference to the disposal of the sewage of the town of Andover, containing the following statement as to your proposed plans : —

“The town of Andover submits two plans for the disposal of its sewage : —

- ‘1. Above the stone bridge, six hundred feet from Main Street, to erect a building, 114 by 42 feet (A), with two sets of double collecting tanks and two filter-beds, thoroughly underdrained, within the building, filtered through a 4-foot chimney 75 feet high, the effluent to have intermittent filtration out of doors through 2½ acres of prepared filter-beds, underdrained, with 3 feet of sand covered with 3 inches of loam, receiving sewage from overdrains, the whole draining into the Shawsheen River.
- ‘2. Such a building (B) on the river below Frye Village without outdoor filter-beds, emptying directly into the Shawsheen River.

"3. Will the Board suggest the size of out-of-door filter-beds deemed necessary to make acceptable our second plant?

"4. Can loam be used over the sand in filter-beds?"

The application was accompanied by plans of the proposed plant at the location first indicated, which is an area of low ground bordering on the right or easterly bank of the Shawsheen River, between Main Street, Harding Street and the Boston & Maine Railroad; and subsequently a report was submitted relating to the proposed method of operation of the plant, and a sample of the sand intended to be used.

The essential features of the plan are settling tanks for the removal of the suspended matters from the sewage by sedimentation; filter-beds having an area of 2,800 square feet, and containing about 5 feet in depth of filtering material, through which it is expected to filter sewage from the settling tanks intermittently at a rate of 3,200,000 gallons per acre daily; and a secondary filter-bed, having an area of 2.3 acres, to be used for the filtration of the effluent from the first-mentioned filters by application to sand beneath a layer of loam. By the alternative plan, the last-mentioned filter-bed may be omitted, but the effluent in either case would be discharged into the Shawsheen River.

The Board has carefully considered the proposed scheme, and finds that it is a thoroughly impracticable one for the disposal of the sewage of the town of Andover.

The settling tanks into which the sewage would be discharged as it came from the main sewer cannot be expected to remove more than a very small portion of the suspended matter. Experiments at Lawrence with reference to the removal of organic matter from sewage by sedimentation have shown that by allowing sewage to settle for four hours about 18 per cent. of the organic matter, as indicated by the albuminoid ammonia, was removed. The consumption of water in Andover for the year 1894 averaged 323,000 gallons per day, and it is not unreasonable to expect that the amount of sewage to be disposed of after the sewerage system has come into general use may be in the vicinity of 200,000 gallons per day. With this quantity of sewage flowing, the time occupied by it in passing through the proposed settling tanks would not average more than two hours, or about one-half the time allowed in the experiments at Lawrence, and during the portion of the day when the flow was greatest the sewage would pass through the tanks in less time; moreover, there would be a constant flow of sewage through the proposed tanks, while in the case of the experiments at Lawrence the liquid was not disturbed.

The in-door filter-beds for the rapid filtration of the sewage after it has passed through the settling tanks are altogether inadequate for the purpose, and would very quickly become clogged, so that the required quantity of sewage could not be made to pass through them.

The proposed rate of filtration for these filters (3,200,000 gallons per acre per day) very greatly exceeds the highest rate ever attained in the filtration of sewage through any sand or gravel in the experiments at Lawrence with the most favorable conditions, even with sewage from which the greater portion of the organic matter had previously been removed; and it may be added that it exceeds even the rate at which Merrimack River water is filtered through the Lawrence city filter.

The effect of applying sewage to the proposed filter at such an excessive rate would be that no opportunity would be allowed for nitrification to become established in the filter, whereby the organic matters would be converted into mineral matters and pass out in the effluent, and the organic matters would consequently accumulate in the interstices of the sand and clog the filter, even if its surface was continually disturbed or scraped.

The purification of sewage by intermittent filtration is not merely mechanical; that is, it is not a straining through fine pores, thereby holding back the organic matters in the sewage, but it is a chemical change, in which the substances are converted into mineral matter, which passes off easily in the purified liquid. To effect this change the experiments at Lawrence have clearly shown that the necessary conditions are very slow motion of very thin films of liquid over the surface of particles having spaces between them sufficient to allow air to be in contact with the films of liquid. With these conditions it is essential that certain bacteria should be present to aid in the process of nitrification; and it has been found that these bacteria come in the sewage at all seasons of the year, and the conditions mentioned appear to be the most favorable for their efficient action.

The proposed filtration area outside the building, to which sewage is to be applied by carriers laid beneath a surface layer of loam, would, on account of the limited capacity of the proposed in-door filters for purifying sewage, receive sewage from which only a small proportion of the organic matter had been removed. While no special chemical or biological difficulties attend the purification of sewage by this form of filter, it has been found both by experiment and in practice that the carriers become clogged with organic matter so that it is necessary to dig up, clean and replace them from time to time, making the cost of maintenance of such a filter greater than where no loam layer is used and sewage is applied directly to the surface of the sand; moreover, experiments with two filters containing the same kind of sand, at Lawrence, to one of which sewage was applied upon the exposed surface of the sand and to the other beneath a layer of loam, was found that the amount of sewage that could be disposed of by the former was more than twice as great as by the latter.

Finally, if sewage should be filtered through properly prepared beds of sand, such as are proposed for use in the filters under consideration, at a rate which will not overtax the capacity of the filter, the effluent would be

sufficiently purified to permit of its discharge directly into the Shawsheen River without further treatment. It may be added that an area of about six acres of such filter-beds would be sufficient for the town in the beginning, but it would be desirable to provide for increasing the area when necessary.

**BROCKTON.** An application was received Aug. 16, 1895, from the mayor of Brockton, for the advice of the Board relative to a proposed plan of "surface drainage" in the Cabot Street section of that city. The Board replied to this application as follows:—

Boston, Oct. 3, 1895.

The State Board of Health has carefully considered the plan for proposed drainage of the Cabot Street system which you presented for its approval August 5, under the provisions of chapter 309 of the Acts of 1888, and hereby approves said drainage system.

**DANVERS.** An application was received Nov. 4, 1895, from the board of health of the town of Danvers, for the advice of the Board relative to the disposal of the sewage of certain morocco factories now discharging into Crane's River in that town by conveying it to an outlet at Danversport. The Board replied to this application as follows:—

Boston, Dec. 5, 1895.

The State Board of Health has carefully considered your application for advice with reference to disposing of the nuisance in Crane's River caused by the discharge into it of manufacturing sewage from three morocco shops. The plan accompanying your application is to divert the sewage from the brook into which it flows at present, and convey it by means of a sewer to a point of discharge in the channel of the Essex Branch River, a tidal stream, near its junction with Crane's River, and you express a doubt as to whether this method of disposal would be satisfactory.

The proposed outlet is close to the village of Danversport, and it appears that there are very extensive flats in the vicinity, which are exposed at low tide. An analysis of a sample of the sewage, collected as it flowed from the present settling tank, shows that the sewage contains several times as much organic matter as is found in ordinary town sewage, and that a large proportion of it is in suspension. With the conditions existing in the vicinity of the proposed outlet, it is probable that organic matter from the sewage would collect on the flats, and cause a nuisance similar to that now existing in Crane's River. The Board does not, therefore, advise the adoption of this method of disposing of the sewage, and it may be added that there appears to be no body of water in the immediate vicinity of the town into which the sewage could be discharged without offence.

It is probable that the sewage from the establishments in question might be disposed of in connection with a general system of sewerage and sewage disposal for the thickly settled portion of the town; and it is suggested that, when a demand arises for such a system, as will doubtless be the case should the town continue to increase in population, it may be found most economical and otherwise satisfactory to dispose of the sewage in connection with a general system of sewage disposal for the city of Salem and the town of Peabody, for which, as you are aware, the State Board of Health is now making investigations.

It is understood, however, that no system of sewerage is at present contemplated by the town, and under the circumstances it becomes important to determine whether it is feasible to purify this sewage to such a degree that it may be discharged into the stream without causing offence. It could probably be done by conducting the sewage into large settling tanks, where the sludge would settle and the liquid could be pumped to a sand and gravel bed and be filtered, and the sludge be frequently removed from the tanks. The Board cannot with present information advise you definitely with regard to this method of disposal, but will assist you in making an investigation of it, if you desire.

**FAIRHAVEN.** The selectmen of Fairhaven applied to the Board on Dec. 16, 1895, for its advice relative to the best practicable method of disposing of the sewage of the village of Fairhaven, submitting a plan for its disposal by one outlet into tide-water at the end of the wharf. The Board replied to this application as follows:—

BOSTON, June 7, 1895.

The plan provides for a system of gravity pipe sewers for collecting the sewage at four points, at each of which Shone ejectors are to be placed, to force the sewage to the outlet above mentioned.

The Board, on May 5, 1891, in reply to a previous application, approved the outlet for the discharge of the sewage of certain public buildings and a small portion of the town, but regards it as an unsatisfactory outlet for a larger quantity of sewage which would be brought to this point by the present plan; and you are, therefore, advised to modify the plan so that the sewage will be carried farther out toward the channel, where it will not pollute the docks or shores. It seems probable that this may be done and a satisfactory outlet secured, without excessive cost, by laying a submerged sewer out from the shore at some point not farther north than the southerly end of Crow Island.

**FRAMINGHAM.** The sewer committee of Framingham applied to the Board Dec. 24, 1894, for its approval, under the provisions of

chapter 403 of the Acts of 1887, of the method of disposal of the water of the under-drain of the main sewers of that town. The Board replied to this application as follows : —

Boston, Feb. 20, 1895.

The Board has considered your application, dated Dec. 24, 1894, in which you ask for its approval of the disposal of the water of the under-drain beneath the Framingham sewers by pumping it to filter-beds located near the present pumping station, as shown on a plan submitted with the application.

A plan for the disposal of this water was presented to the Board Jan. 23, 1893, which provided for diverting it entirely from the water-shed of the Boston water supply by pumping it over the divide into Bannister Brook. Concerning that plan the Board advised that it was a permissible method of disposing of the water, but that filtration might be necessary if the character of the water should deteriorate.

The plan now proposed provides for the disposal of the water of the under-drain by filtration on land within the water-shed of the Boston water supply, and has the advantage of saving to this supply a quantity of water which under the former plan would be lost; but it has the disadvantage that the nitrates in the filtered water will have a slight tendency to promote the growth in Cochituate Lake of the organisms which impart to water disagreeable tastes and odors.

In view of all the circumstances, the Board is of the opinion that the disposal of the under-drain water by the proposed plan is not objectionable from a sanitary point of view, and is an appropriate method of disposing of this water.

Samples of earth sent in by you from three test pits dug in the proposed area have been examined, and the samples from two of them have been found to be of satisfactory quality, except near the surface, for filtration purposes, but samples from the remaining pit consisted of very fine material. In constructing the filter-beds care should be taken to locate them where the material is porous and suitable for filtration. The plan provides for the preparation of an area of about one acre, but it would be desirable to make provision for extending this area in the future if it should be found necessary.

SPRINGFIELD. The mayor of Springfield applied to the Board Aug. 23, 1895, for advice relative to the extension of certain sewers to the Connecticut River, and the construction of new sewers having their proposed outlets in the river. The Board replied to this application as follows : —

**Boston, Oct. 3, 1895.**

The State Board of Health received from you on Aug. 23, 1895, an application for its advice relative to the proposed extension to the river channel of the sewer outlets in Worthington and Union streets, which now discharge at the bank of the river, and the construction of a new sewer in Conhill street, accompanied by plans showing details of the proposed extensions and the results of float experiments made to determine the direction of currents in the river opposite the city.

The discharge of sewage at the bank of the river has caused a serious muling of the shores, so that at times of low water they are very offensive. The proposed extensions will carry the sewage away from the river bank well out into the stream, and the points of discharge indicated appear to be so located that the sewage will have passed the city and become well diluted before returning to the shores, and their adoption is recommended. It would, however, be well to avoid the up-turning of the discharge pipe at the end, and have a free outlet, with no depressed portion of the pipe in which solids from the sewage may be deposited.

**TWICKSBURY.** An application was received from the board of health of Twicksbury, April 9, 1895, for advice relative to the disposal of the sewage of a portion of that town into the Concord river. The Board replied as follows:—

**Boston, Oct. 3, 1895.**

The State Board of Health received from you on April 9, 1895, an application with reference to a partial system of sewerage in the portion of Twicksbury bordering on the Concord River, accompanied by a profile showing a proposed sewer in Whitehead and Warnock streets, ending in the Concord River, near the boundary between the town of Twicksbury and the city of Lowell.

The Board has caused an investigation of the proposed plan to be made, and has deemed it necessary, in view of the existing conditions, to take into consideration the whole subject of sewerage and sewage disposal for the rapidly growing portion of the town near to Lowell. Aside from the locality to be drained by the proposed sewer, there are other localities in a part of the town, containing a much larger population, which appear to be already in need of sewerage facilities, or, with a continued rapid increase in population, likely to need them in the near future.

While the discharge of sewage from the proposed sewer, under present conditions, into the Concord River, might not cause any serious harm, the board is of the opinion that no large amount of sewage can safely be disposed of in this way, owing to the conditions that prevail in the vicinity of the river below, where there are densely populated sections of the city of

Lowell in the immediate vicinity of the stream. It is also worthy of note that the city of Lowell has been compelled by the courts to discontinue the discharge of sewage into the Concord River, above the last dam.

In view of all the circumstances, the Board advises that a more extended investigation be made of the subject of sewerage and sewage disposal for this rapidly growing portion of the town of Tewksbury, both in order that sewers may be constructed in the beginning in accordance with some well-defined plan for the district as a whole, and in order that a suitable method of disposing of the sewage be adopted in the beginning.

It is suggested that, in connection with investigations of methods of disposing of the sewage of this portion of the town, there appear to be two feasible methods which are worthy of investigation, — one by disposal on filter-beds of sufficient area, as at Framingham, Marlborough and several places in the State, and the other by disposal in connection with the sewerage system of the city of Lowell.

The Board will advise you further in this matter when you have additional information to present.

**WEBSTER.** The sewer commissioners of Webster applied to the Board Oct. 15, 1895, for its advice relative to a proposed system of sewerage and sewage disposal for that town, having its outlet into French's River, at a point below the bridge of the Southbridge branch of the New England Railroad. The Board replied to this application as follows : —

Boston, Jan. 3, 1896.

From investigations made by the Board, through its engineers, it appears that French's River is already considerably polluted by manufacturing sewage. Below the proposed sewer outlet there are several millponds which afford a favorable opportunity for the solid portions of the sewage and manufacturing wastes to settle and become offensive. Near each of these millponds is a village, the inhabitants of which would necessarily be affected by the pollution of the river and the deposits of organic matter on the bottoms and sides of the ponds.

Under the circumstances, the Board does not advise the disposal of the sewage of Webster as proposed, by discharging it without treatment into French's River, but advises a further investigation of the subject of sewage disposal, with a view to purifying the sewage in such a manner that the effluent may subsequently be discharged into the river without danger of causing offence to the inhabitants of the villages on the river below.

A tract of land is referred to in the report of your engineer in connection with the disposal of the sewage by filtration or irrigation. The Board would advise a thorough investigation of the areas suitable for the dis-

al of sewage in the vicinity of the river below the proposed outfall, determine the location and extent of the areas available for sewage ation.

The Board will advise you further in this matter when you have additional information to present.

**STATE FARM AT BRIDGEWATER.** An application was received in the superintendent of the State Farm at Bridgewater for the advice of the Board relative to the disposal of the sewage of that institution. The Board replied as follows : —

Boston, Dec. 14, 1895.

The State Board of Health has carefully considered your application for advice as to the disposal of the sewage of the State Farm, and has caused examination of the territory in the vicinity of the farm to be made by engineers.

The present method of disposing of the sewage after leaving the buildings is to convey it to settling tanks just outside the northwesterly corner of the grounds of the institution, from which it is allowed to overflow and down the hill into a small brook, which is very badly polluted thereby, thence into the Taunton River.

While you have a large area of land upon which sewage might be used for irrigation, and some advantages to the crops be obtained thereby, the soil is not favorable to absorbing a large amount of the sewage, and would have to be applied with a good deal of care to prevent its becoming noxious.

North of the institution, beyond the brook and about a mile and a quarter from the buildings, you have some land which appears to be adapted to agriculture; and the Board would advise that you cause an examination to be made, to determine whether this area is available for the disposal of the sewage of the institution at a reasonable expense, and whether the area of available porous material is of sufficient extent to filter all of the sewage of the institution, and produce an effluent that may be discharged into the Taunton River without objection.

#### **POLLUTION OF INLAND WATERS.**

**THE BLACKSTONE RIVER.** An application was received Aug. 17, 1895, from the selectmen of Millbury, asking the advice of the Board "in reference to the pollution of the Blackstone River by sewage and by the effluent from the sewage precipitation works

4, averaged about 12,500,000 gallons per day, and that a portion of sewage at times of high flow in the brook escapes into the river without treatment.

The population of the city of Worcester has increased since 1886 about ty-nine per cent., and the total length of sewers has increased during t time about eighty-seven per cent., from which it would be reasonable conclude that the amount of sewage discharged by the sewers has ible. It appears from the report of the superintendent of sewers that, an average, about fifty per cent. of the organic matter is removed from sewage by treatment at the precipitation works; and, taking into consideration the fact that a portion of the sewage escapes into the river without treatment, it would be expected that the amount of organic matter discharged into the river in the sewage and effluent of the city of Worcester is great as in 1886.

As a means of determining the condition of the river from time to time, Board has continued its regular examination; and, in order to compare condition of the river in 1895 with that existing before the last reply made, the Board has caused a special examination of the river to be de by means of numerous chemical analyses of samples collected at ous points and at frequent intervals during the week ending Sept. 11, 1895, corresponding to an examination made in the week ending July 29, 1891. From the results of these investigations the Board finds that the dition of the river below the point of discharge of the effluent from the cipitation works and in the town of Millbury is practically the same as was at the time when the last reply was made.

The Worcester precipitation works have been conducted under the direction of skilled engineers and chemists, and the percentage of organic matter removed from the sewage treated at the works, even on the scale required, has doubtless been as great as it is practicable to attain by chemical precipitation alone. As the city grows and the amount of sewage increases, the amount of organic matter discharged into the river will also necessarily increase, unless a more complete purification of the sewage is de.

**LAKE QUINSIGAMOND.** The selectmen of Shrewsbury called the attention of the Board July 1, 1895, to the possible pollution of Lake Quinsigamond (which lies partly in Shrewsbury) by the sewage of the Worcester Lunatic Hospital. The Board replied to this communication as follows:—

Boston, Dec. 5, 1895.

The State Board of Health has considered your application with reference to the pollution of Lake Quinsigamond by the sewage from the

Worcester Lunatic Hospital, and has caused an examination of the premises to be made.

From present information the Board is not prepared to give an opinion in this matter, but will cause a further investigation to be made during the coming year, and will then inform you as to its conclusions.

LAKE CHAUNCY. The following communication was received from the selectmen of Northborough Sept. 17, 1895:—

NORTHBOROUGH, MASS., Sept. 17, 1895.

GENTLEMEN :— For a number of months the sewage of the Westborough Insane Hospital has been discharged directly and without treatment into Lake Chauncy, one of the great ponds of the State, and within the limits of this town.

We respectfully ask you to examine the premises, and if, in your opinion, the conditions are prejudicial to health or comfort, to take such action as may be necessary.

Respectfully,

(Signed)

CYRUS H. MENTZER,

EDWIN S. COREY,

JAMES S. LEARNED,

*Selectmen of Northborough.*

In consequence of this letter the following communication was sent to the trustees of the Westborough Lunatic Hospital, and a copy of the same was also sent to the selectmen of Northborough :—

Boston, Dec. 5, 1895.

Information has been received from the selectmen of Northborough that for a number of months the sewage of the Westborough Insane Hospital has been discharged directly and without treatment into Little Chauncy Pond. The investigations made by the Board, through one of its engineers, show that such is the case, and that there is strong evidence that this condition has existed for a considerable time.

This method of disposal of the sewage causes the serious pollution of Little Chauncy Pond and the stream flowing from it through Northborough into the Assabet River, and is a menace to the public health. It is not, in any sense, a proper method of disposing of the sewage from this institution, and should not be allowed to continue.

In 1887 the trustees of the hospital requested the Board to examine the sewerage system of the hospital and recommend a proper method of disposal. After careful examination of the premises by the engineer of the

ard, a reply was made to the effect that the most suitable method of disposal was upon land situated on the opposite side of the brook leading from auney Pond to Little Chauncy Pond.

A few months later a general plan for a system of subsurface disposal was presented by you through your engineer, which provided for disposal on a tract of land upon the side hill north-westerly from the hospital. On inspection of the area upon which it was proposed to dispose of the sewage, it did not appear to the Board that it was adapted to the purpose; but after giving a hearing, at which your engineer explained the nature of the ground on which it was proposed to dispose of the sewage, and the general features of the plan, it appeared from his account that the material, shown by the trial pits, proved to be so much better adapted to the filtration of sewage than inspection of its surface promised, that the committee on water supply and sewerage of the Board saw no reason to doubt that the sewage of the hospital could be disposed of upon it without risk to the health of the inmates or the public. Your engineer declined to explain details of the method of distribution, and the Board expressed no opinion upon this subject.

Since it now appears that the sewage is not purified by this method, and is very improbable that with such soil as that of which the field is composed the sewage could be properly disposed of under the most favorable circumstances by subsurface irrigation, the Board advises that you convey the sewage across the brook, and dispose of it by filtration upon the tract of land which investigation has shown to be available, in general accordance with the advice of the Board contained in the communication addressed to you May 9, 1887, previous to the adoption of the present system.

The Board will, on application, advise you further as to the details of a plan for the satisfactory disposal of the sewage, if you desire it.

## MINATION OF WATER SUPPLIES.

---

---

# EXAMINATION OF WATER SUPPLIES.

---

## EXPLANATORY NOTE.

The systematic examination of the water supplies of the State was begun June 1, 7, and has been continued up to the present time. The results of the investigations made during the first two years were published in a special report of the Board upon the Examination of Water Supplies (1890), and of those made during succeeding years in the annual reports of the Board beginning with the 1890 (Twenty-second Annual) report.

The special report contains a description of each of the water supplies in the State existing at the date of that report, and the annual reports contain descriptions of new works and changes in existing works.

In all of these reports an alphabetical arrangement by towns has been adopted. Records of water supply are tabulated under the name of the town supplied, other records under the name of the town in which they are situated. The analyses of waters from the larger rivers not used as sources of water supply are given in a subsequent tabulation, headed "Examination of Rivers."

The method of making the chemical examinations remains unchanged, and the results are presented in the tables of this report in the same form as in the last one. The samples of water are usually received at the laboratory from twenty-four to thirty-eight hours after collection. All surface water and such samples of ground water as contain suspended matter are filtered through filter-paper before determining the color, the residue on evaporation and the albuminoid ammonia in solution. Ground waters which are perfectly clear and colorless when drawn from the well and become turbid and colored on standing, in consequence of the oxidation of the iron which they contain. In these waters the residue on evaporation is determined without filtration, since this iron is an essential and not an accidental ingredient in the water. In the changes which accompany the oxidation of the iron in waters of this character, they become first cloudy (well described by the word "opalescent") and finally deposit a precipitate of oxide of iron. In the cloudy condition waters have a distinct color, which while it does not have the same significance as in the case of surface waters, and is only a passing phenomenon, is, nevertheless, of great value as showing a color which the water may assume while the oxidation of the iron is in progress. When the iron is all oxidized and precipitated the water may become colorless again. Explanatory notes will be given for waters of this kind in connection with the tables of analyses.

The color of water is expressed by numbers which increase with the amount of

The standard used is nesslerized ammonia, as described on page 531 of the Special Report upon the Examination of Water Supplies, 1890, and on page 329 of the Annual Report for 1892. Boston water, as drawn from a tap at the Institute of Technology, had an average color in 1895 of 0.72. Other water supplies in the State have had an average color of from 0 to 1.30.

In cases where examinations of a source have been made with considerable regularity for several years, the averages of the chemical analyses of each year are given.

There was no change in the method employed in the microscopical examination of water between Nov. 6, 1890, and Dec. 1, 1895. The method employed between those dates is fully described in the Twenty-third Annual Report of the Board for the year 1891 (pages 395-421). Before Nov. 6, 1890, the methods employed were less perfect, so that a smaller proportion of the total number of organisms present in the water was separated from it and observed under the microscope; and, before drawing conclusions from a comparison of the microscopical examinations of waters made before and after this date, the explanatory note on page 70 of the Twenty-second Annual Report for 1890 should be read.

Since Dec. 1, 1895, the method for the microscopical analysis of water has been considerably improved by discarding the ordinary glass funnels previously employed and substituting funnels which have been constructed with stems of equal calibre, to give equal rates of filtration, and with steeper sides, so that those organisms which are of a gelatinous character will be less liable to adhere to the sides of the funnel. By the use of these funnels variations in the numbers of organisms found, which may be caused by dissimilar slopes of the sides of the funnels and unequal rates of filtration, are avoided.

To indicate the amount of the so-called *Zoöglæa* observed, the number of individual masses is not counted, but an area equal to 2,500 square microns, or .0025 square millimeters, has been adopted as an arbitrary unit.

In publishing the results of the microscopical examinations the same system is followed as last year. The plants observed are classified in four groups, viz.: Diatomaceæ, Cyanophyceæ, Algæ and Fungi. The animals observed are grouped as Rhizopoda, Infusoria, Vermes and Crustacea.

The names of the different genera in each group are given with the numbers of each per cubic centimeter, except that, to avoid making the tables excessively long, they are omitted when present only in very small numbers. It is not feasible to make with regard to omissions a single rule which will apply to all cases, because it is desirable to include smaller numbers of animals than of plants, and of the larger animals than of animals generally. Moreover there are exceptional cases in which it is desirable to indicate the presence of even very small numbers of the more important plants or animals. Two general rules, however, have been adopted in printing the results, viz. :—

1. All genera of plants are included in which the total number observed in twelve months amounts to 6 or more per cubic centimeter, or, in other words, averages as much as 0.5 per month.

2. All genera of animals are included in which the total number observed in twelve months amounts to 1.5 or more per cubic centimeter.

The larger microscopic animals, such as some of the Crustacea, are included, even when present only in very small numbers.

Fractions are generally omitted from the table, the nearest whole number of organisms per cubic centimeter being given. Where the total number of organisms observed is 0.5 or less, the fact that the organism was present is usually indicated by the abbreviation "pr.," but in the case of the larger organisms very small fractions are given.

## EXAMINATION OF WATER SUPPLIES.

### WATER SUPPLY OF ABINGTON AND ROCKLAND.

*Chemical Examination of Water from Big Sandy Pond, Pembroke.*

\* June to October, six samples.

† January to April, five samples.

‡ March.

§ March and April.

|| February, March and April.

urns to analyses of 1895: Odor of the first sample distinctly vegetable, becoming unpleasant on g; of the second, faintly aromatic, becoming distinctly vegetable and unpleasant on heating; of ird, very faint or none, becoming faintly vegetable on heating. — The samples were collected faucet at the pumping station.

### Microscopical Examination.

e total number of organisms per cubic centimeter found in each sample was as follows: No. 4; No. 12061, 88; No. 14123, 717, consisting chiefly of *Dinobryon* and *Synedra*.

## ACTON.

## ACTON.

*Chemical Examination of Water from Tubular Test Wells in Acton.*

[Parts per 100,000.]

| 14798   | Aug. 10             | Distinct, clayey. | Heavy, sandy.  | .04    | 5.50                    | .0002    | .0000       | .22       | .0040       | .0000     | .0783            | 2.6       | .0100 |
| 15166   | Sept. 13            | Decided, clayey.  | Cons., earthy. | .04    | 6.70                    | .0000    | .0010       | .22       | .0030       | .0000     | .0406            | 2.6       | .0370 |

Odor, none. — The samples were collected from tubular test wells in Acton, which were located approximately as follows: No. 14797, 250 feet east of the town line between Acton and Boxborough and about 350 feet north of Massachusetts Avenue. No. 14798, about 340 feet east of the same boundary line and 500 feet north of Massachusetts Avenue. No. 15166, about 35 feet east of the boundary line and 280 feet north of Massachusetts Avenue. The analyses were made in connection with an investigation for a water supply for the town of Acton.

*Microscopical Examination.*

No organisms.

*Chemical Examination of Water from Fort Pond, Littleton, and Magog Brook and Magog Pond, Acton.*

[Parts per 100,000.]

| 15784   | 1895.<br>Dec. 20    | V. slight.  | V. slight. | .30    | 3.10                           | 1.20                 | .0046    | .0170       | .0136      | .0034           | .23       | .0100          | .0001     | .3311            | 6.5       |
| 15785   | Dec. 20             | V. slight.  | Cons.      | .57    | 3.30                           | 1.55                 | .0004    | .0170       | .0126      | .0044           | .22       | .0100          | .0000     | .5390            | 6.5       |
| 15786   | Dec. 20             | V. slight.  | Slight.    | .10    | 2.45                           | 1.30                 | .0028    | .0332       | .0296      | .0036           | .30       | .0000          | .0000     | .2141            | 6.3       |

Odor, none; on heating, the first two samples had a faintly vegetable odor. — The samples were collected as follows: No. 15784, from Fort Pond, about 30 feet from the shore at the southerly end; No. 15785, from Magog Brook, about 50 feet above the road leading from Acton Centre to North Acton and about one mile below Magog Pond; No. 15786, from Magog Pond, near the road at the easterly end.

*Microscopical Examination.*

The total number of organisms per cubic centimeter found in each of these samples was as follows: No. 15784, 123; No. 15785, 43; No. 15786, 41.

ADAMS.

## WATER SUPPLY OF ADAMS FIRE DISTRICT, ADAMS.

The advice of the State Board of Health to the Adams Fire District with reference to an additional supply of water may be found pages 10-13 of this volume.

The present sources of supply are Bassett and Dry brooks, one of which there is a small reservoir. An auxiliary supply is obtained from a well of the Renfrew Manufacturing Company in the village, and during the drier portion of 1895 a small additional quantity of water is said to have been pumped from tubular wells at the Zylonite Works in the northerly portion of the village.

The results of analyses of samples of water from these sources and from other sources investigated with reference to an additional water supply for the Fire District are given in the following tables.

*Chemical Examination of Water from Bassett Brook, Adams.*

[Parts per 100,000.]

| Date of Collection. | APPEARANCE. |           |        | RESIDUE ON<br>EVAPORA-<br>TION. |                      | AMMONIA. |             |            |                 | Chlorine. | NITROGEN<br>AS |           | Oxygen Consumed. | Hardness. |

| Apr. 17             | None.       | Slight.   | .05    | 2.70                            | 1.00                 | .0000    | .0048       | .0042      | .0006           | .07       | .0600          | .0000     | .1698            | 1.1       |
| Sept. 8             | None.       | V slight. | .08    | 6.40                            | 0.00                 | .0000    | .0014       | -          | -               | .10       | .0110          | -         | -                | 3.2       |
| Sept. 11            | Slight.     | Slight.   | .07    | 7.20                            | 0.00                 | .0000    | .0042       | .0038      | .0004           | .12       | .0130          | .0000     | .1092            | 5.0       |

Odor, none. — The first sample was collected from a tap in the town and represents water from Bassett Brook; the second, from Bassett Brook just above the reservoir; the third, from the reservoir.

*Microscopical Examination.*

No. 15083 was not examined. An insignificant number of organisms was found in the other samples.

Odor of 14390, faintly vegetable and disagreeable, disappearing on heating; of the other samples, none.—The samples were collected as follows: No. 14305 from a test pit 30 feet from the Hoosac River on the west side of the Boston & Albany Railroad, 2,000 feet south of the railroad bridge over the Hoosac River, just above Cheshire Harbor; No. 14384, from the west spring of the Brown Paper Company; No. 14390, from Follett's Spring, opposite Follett's lime works, in the northerly part of Adams; the remaining samples, from test wells in the valley of the Hoosac River, about half a mile above Cheshire Harbor.

*Microscopical Examination.*

No. 14305. Miscellaneous, *Zoëglæa*, 4,600.

No. 14388. Diatomaceæ, *Synedra*, 1.

No. 14390. Diatomaceæ, *Diatoma*, 1; *Navicula*, 4; *Pinnularia*, 1; *Synedra*, 80. Total, 86.

No organisms were found in the remaining samples.

**WATER SUPPLY OF AMESBURY.—POWOW HILL WATER COMPANY.**

The advice of the State Board of Health to the Powow Hill Water Company relative to taking an additional supply of water from the pond near Main Street in that town may be found on pages 13 and 14 of this volume. Analyses of samples of water collected from the present and other sources, in connection with the investigation for an additional supply, are given in the following tables.

**AMESBURY.***Chemical Examination of Water from Tubular Wells supplying Open Basins near Main Street.*

\* July.

† November.

‡ January to April.

§ February, March and April.

NOTE to analyses of 1895: Odor, faintly vegetable. — The samples were collected from a faucet at the pumping station.

*Microscopical Examination.*

The average number of organisms per cubic centimeter found in these samples was 96, consisting chiefly of *Synedra* and *Dinobryon*.

## WATER SUPPLY OF ARLINGTON.

Works for the supply of the higher portions of the town were completed in the early part of 1895. The supply is drawn from twenty-five 2½-inch tubular wells located at the edge of the Great Meadows, near the Boston & Maine Railroad, opposite the East Lexington station. The wells have an average depth of about 35 feet. Water is forced from the wells to a covered iron tank, 40 feet in diameter and 60 feet high, situated on Arlington Heights. The capacity of this tank is 565,000 gallons.

ARLINGTON.

The advice of the State Board of Health to the town of Arlington, with reference to this source of water supply, may be found on pages 7 and 8 of the annual report for 1894, and analyses of samples of water collected during the investigations for an additional supply may be found in the annual reports of the Board for 1892 and 1893.

Odor of the first sample, very faintly earthy, becoming stronger on heating; of the second, decidedly tarry; of the third, distinct, fragrant, disappearing on heating; of the last, none, becoming distinctly vegetable and unpleasant on heating. — The samples were collected from hydrants on dead ends, the first and last on Forest street; the second 400 feet off force main from the pumping station to the sandpipe; the third, on Robert Street. The hydrant on Robert Street was flushed the day before the sample was collected.

Odor, none. — The first and second samples were collected from a faucet at the pumping station; the last, from the well.

*Microscopical Examination.*

An insignificant number of organisms was found in these samples.

BARRE.

WATER SUPPLY OF BARRE.

Population in 1895, 2,278. The works are owned by the Barre Water Company and were completed in October, 1895. The source of supply is a small storage reservoir in the northerly part of the town in which the water from several springs in the vicinity is collected. Water from springs in another watershed is also diverted to this reservoir by means of 700 feet of open trench and about 100 feet of earthen pipe.

The combined watersheds tributary to the storage reservoir contain about 275 acres of hilly country, half of which is wooded, the remainder being largely pasture land. There are a few houses on the watersheds.

The storage reservoir was made by excavating in a depression and building a dyke around the edges, material for the dyke being taken from the excavation. The bottom of the reservoir is of hard pan. The area when full is 4.25 acres, its depth 10 feet, and its capacity 1,000,000 gallons.

Water is distributed by gravity. Distributing mains are of cast iron and service pipes of wrought iron lined with cement.

The advice of the State Board of Health to the Barre Water Company relative to taking water from this source as a public water supply may be found on pages 8 and 9 of the annual report for 1894, and analyses of samples of water collected during the investigation with reference to a water supply may be found on page 83 of the same volume.

WATER SUPPLY OF BELMONT.

(See *Watertown.*)

WATER SUPPLY OF BEVERLY.

(See *Salem.*)

BILLERICA.

The advice of the State Board of Health to J. Nelson Parker and others of the town of Billerica, with reference to the use of Nutting's pond in that town as a source of public water supply, may be found on pages 14 and 15 of this volume. Analyses of samples of water collected at different parts of the pond are given on the following page.

**BILLERICA.***Chemical Examination of Water from Nutting's Pond, Billerica.*

WATER SUPPLY OF BOSTON.

The results of analyses of water from reservoir No. 6 given on pages 98–101 indicate that the quality has remained about the same last year, that there has been no large growth of organisms and that during the period of summer stagnation there has been only a comparatively small accumulation of the products of decomposition at the bottom of the reservoir.

The color of the water supplied to the city from the Cochituate works in 1895, as indicated by the averages of analyses given on page 115, again shows a slight increase over the previous year. The higher color of recent years is due, as noted in previous reports, to the increasing proportion of Sudbury River water supplied to the city.

As stated in the annual report for 1894, the odor of the water of Mystic Lake became extremely offensive in the latter part of 1894 and early in 1895, so that many of the water consumers found it necessary to obtain well or spring water for drinking. This condition continued through the winter for a period of several weeks, but the quality of the water improved with the breaking up of the ice on the lake.

The water of Stony Brook above Reservoir No. 3, and of the reservoir itself, has been unfavorably affected, during this year as it, by work incidental to the construction of Dam No. 5 and the tipping of the basin to be formed by this dam. In consequence of this work the use of water from reservoir No. 3 has been avoided, as far as possible.

## BOSTON.

SUDBURY RIVER SUPPLY.—*Chemical Examination of Water from Indian Brook at Head of Reservoir No. 6, Hopkinton.*

NOTE to analyses of 1895: Odor, generally vegetable and frequently also mouldy. — The samples were collected from the brook, at its entrance into Reservoir No. 6.

*Microscopical Examination.*

The average number of organisms per cubic centimeter found in these samples was 75.

SUDBURY RIVER SUPPLY.—*Chemical Examination of Water from Reservoir No. 6, Ashland, collected near the Surface.*

NOTE to analyses of 1895: Odor, vegetable, frequently also unpleasant or disagreeable. The iron was determined in five samples, the average amount in parts per 100,000 being .0139. — The samples were collected from the reservoir near the dam. For monthly record of height of water in this reservoir see table at end of Boston analyses.

\* June to December.

NOTE to analyses of 1895: Odor, vegetable.—The samples were collected from the brook at the entrance into Reservoir No. 4.

*Microscopical Examination.*

The average number of organisms per cubic centimeter found in these samples was 68.

## BOSTON.

RIVER SUPPLY.—*Chemical Examination of Water from Reservoir No. 4, Ashland.*

[Parts per 100,000.]

\* June to December.

analyses of 1895: Odor, vegetable, generally stronger on heating. The iron was determined as, the average amount in parts per 100,000 being .0075.—The samples were collected near the gate-house, 1 foot beneath the surface. For monthly record of height of reservoir see table at end of Boston analyses.
